## 1. Introduction

### 1.1 DCS 500 programming

This manual is describing programming of the DCS 500 standard DC-drive.

Programming is done by setting the DCS 500 pointers. They are used to define connections between function blocks and to set operating values for standard and application function blocks.

DCS 500 drive application can be created in three different ways:

- with a PC-based engineering tool, the GAD
- with the CDP 310 control panel
- with a PC-based commissioning tool, the CMT/DCS 500.

CDP 310 panel and CMT/DCS 500 should be used only for small size applications. GAD is the right tool for larger applications.

Drive application created with the GAD is downloaded to the DCS 500 drive with the CMT/DCS 500 commissioning tool.

The GAD can also generate diagram files for the CMT/DCS 500. These files contain all graphical information about the application, so that the CMT/DCS 500 can display the function block application in the same format as it was displayed in the GAD.

CDP 310 panel and CMT/DCS 500 commissioning tool can be used to make on-line changes to the drive application.

### 1.2 DCS 500 Function Blocks

#### General

Function blocks are software implemented elements which perform some basic function. With them the DCS 500 user can create small and medium size application programs to meet the needs of his drive application.

#### The Programming Language

The Function Block (FB) is the smallest unit of the application programming language. Each FB performs a complete function, such as a logical AND gate, a timer or a feedback control block.

#### Call

Each block has an unique call name that identifies its type and instance number (e.g. ADD2\_222). The block is selected with the individual block instance number.

## Graphic Symbol

Each Function Block has a graphic symbol. Normally, the call name of the block is written in the uppermost part of the symbol. For certain functions, e.g. AND and OR, the name is replaced by a special symbol.

The instance number of the block is written above the symbol.

## Connections of Function Block Inputs and Outputs

Only inputs and outputs with the same data type (e.g. integer or Boolean) should be interconnected.

The GAD-tool, CMT/DCS 500 or the operators panel make no checks on the data type of connected pins. The responsibility of correctly made connections is left to the user.

## 1.3 Function Block Libraries for the DCS 500

The function block libraries of the DCS 500 contain a fixed set of function blocks to be used in different drive applications.

In the GAD engineering tool there are four sub-libraries for the DCS 500:

1. Standard Program FBs
2. Application Program FBs
3. Application Information FBs
4. Template FBs

### Standard Program FBs

These Function Blocks describe the different functions of the DCS500 Standard Program. There are blocks like Analog Input1, Ramp and Speed Control.

These functions are described within the DCS 500 documentation. This document describes in detail only the Application Program blocks.

The user cannot affect the execution on Standard Program FBs. It is handled totally inside the DCS 500 Drive Program. The user is only able to set the block parameters and connect the inputs.

Simple drive applications can be done by using only Standard Program FBs.

### Application Program FBs

If the user has a drive application which cannot be created only with Standard Program FBs, he can use the Application Program FBs.

Application Program FBs are general purpose blocks which can be connected to each other and to Standard Program FBs to create a complete drive application.

When the application is created, the user has to specify which blocks are used, the connections between blocks, the execution order and the execution interval.

## Application Information FBs

These FBs are used to give some information about the application in hand and about the DCS 500.

## Template FBs

These FBs are used to create the template which is used by the GAD engineering tool, when the application is designed.

The user is able to customise these FBs to better suit his needs and his documentation standard.

## 1.4 Programming with the FB Language

When programming a DCS 500 drive application with the GAD-tool, FBs are selected from the DCS 500 FB libraries and copied to the application design template. The Function Blocks are then interconnected to define the data flow between the FBs and correct values are entered for the FB parameters.

The compiler of the GAD-tool translates the program into a load file, which is loaded into the DCS 500 with the CMT/DCS 500-tool.

Also the CDP 310 operators panel or the CMT/DCS 500 can be used to create an application. This is convenient if the application is quite small.

### FB Application tasks

The number of function block instances is fixed. The instance numbers for each block type are presented in the detailed description of the block.

There are three cyclic tasks with different intervals available:

Task1:	5 ms
Task2:	20 ms
Task3:	200 ms

A scheduler program will call all blocks in the execution list of the task one after another. The execution order is the same as the order of the blocks in the list. The execution order is defined when the application is created with the GAD-tool or with the operators panel.

Execution order of a function block is defined so that the first block in a task gets the execution order value **1**. Other blocks in the task get the value which is equal to the block instance number of the preceding block.

When GAD is used to create the application, the execution order is defined with symbol attribute values. Each block has a special attribute **ExecutionOrder** whose value must be set when the block is added to the application.

Also the task where the block is added must be set with the **Task** attribute. Execution order and task are not needed for Standard Program FBs.

When the panel or the CMT/DCS 500 is used, the user is prompted for the task number and execution order.

Each task can have a different maximum number of blocks:

Task1:	25
Task2:	100
Task3:	250

Fast Tasks 1 and 2 should be used only when Task 3 is too slow for the application. A FB in Task2 creates 10 times more processor load compared to the same FB in Task3.

Only Application Program FBs are entered to the execution order list. Standard Program FBs are executed by the DCS 500 Drive Program in a fixed order.

It is not possible to synchronise the execution of Application Program FBs and Standard Program FBs.

## 1.5 Starting and stopping of the FB application

When the application is downloaded to the DCS 500 from the CMT/DCS 500 or when it has been created with the panel or the CMT/DCS 500, the application is normally not running and function blocks are not executed.

The application is started by setting the parameter 2504, FB\_APPL\_ENABLE, to value 1 (ENABLE). This can be done either with the panel or the CMT.

The application is stopped by setting the parameter 2504, FB\_APPL\_ENABLE, to value 0 (DISABLE). When the application is stopped, outputs of the application program function blocks are not updated.

It should be carefully considered, what stopping of the application means for the whole drive application. The application should be built so that safety functions are not disabled, when the application is not running.

## 1.6 Application backup function.

The application is saved to the parameter backup memory together with standard program parameters.

The parameter backup memory has two parameter sets for standard program parameters and one set for application parameters.

When standard program parameter set 1 or 2 is saved, also application parameters are saved.

Application parameters are read only when specifically ordered with the panel or the CMT/DCS 500.

At power-up standard program set 1 and application parameters are read.

Notice that if the application was stopped, when the parameters were saved, the application is not automatically started when the parameters are read from the backup memory at power-up or when specifically ordered.

## 1.7 Programming with the operator's panel

The function block application can also be created with the operator's panel, at least when the application is quite small.

The panel has a special mode for FB application programming. This mode is entered by pressing the FUNC-key and after that the DOUBLE ARROW-key. The panel will display the text: FB PROGRAMMING. Press ENTER-key to start FB programming.

The display will show following texts:  
FB PROGRAMMING  
FUNC MENU:  
TASK EXECUTION LISTS

In this mode you can select between five sub-functions by pressing ARROWUP-or ARROW DOWN-key. These functions are:

- TASK EXECUTION LISTS
- ADD FUNCTION BLOCK
- DEL FUNCTION BLOCK
- MOVE FUNCTION BLOCK
- TERMINATE FB PROGR!

### **Task Execution lists**

You can select this function by pressing the ENTER-key when the text TASK EXECUTION LISTS is on the bottom row.

Next you have to enter the task number. Select 1, 2 or 3 with the single arrow-keys and press ENTER-key.

Now you can go through the list of function blocks in the selected task in the order they are executed. Each block is shown on the bottom row:

```
TASK EXECUTION LISTS  
TASK[3]  
1 :[INV (10)]
```

1 means the position in the execution order list. On the brackets there is the function block type and instance number. LAST (0) means the end of the execution order list. The LAST entry in the list marks the end of task. FBs which come after LAST are not executed.

You can go back to the FB programming menu by pressing the ENTER-key.

### **Add function block**

You can select this function by pressing the ENTER-key when the text ADD FUNCTION BLOCK is on the bottom row.

Next you have to enter the task number. Select 1, 2 or 3 with the single arrow-keys and press ENTER-key.

Now you can go through the list of available function blocks by pressing arrow keys. Single arrow keys are used to select the instance number and double arrow keys to select the block type. The function block is shown on the bottom row:

```
ADD FUNCTION BLOCK
```

```
EXTER FB NUMBER  
INV (10)
```

INV means the function block type and the instance number is in parentheses.  
Select the block by pressing the ENTER-key.

Next step is to enter the position of the new block in the execution order list. Function blocks in the execution order list are shown on the bottom row:

```
ADD FUNCTION BLOCK  
EXTER FB TASK POS:  
1: [INV (34)]
```

1 means the position in the execution order list. On the brackets there is the function block type and instance number. LAST (0) means the end of the execution order list.

Press the ENTER-key when you have the correct position on the display. The new function block will be added **before** the block shown on the display.

### Delete function block

You can select this function by pressing the ENTER-key when the text DEL FUNCTION BLOCK is on the bottom row.

Next you have to enter the task number. Select 1, 2 or 3 with the single arrow-keys and press ENTER-key.

The function block to be deleted is selected from the execution order list. Function blocks in the execution order list are shown on the bottom row:

```
DEL FUNCTION BLOCK  
EXTER FB TASK POS:  
1 :[INV (10)]
```

1 means the position in the execution order list. On the brackets there is the function block type and instance number. LAST (0) means the end of the execution order list.

Press the ENTER-key when you have the block to be deleted on the display.

### Move function block

You can select this function by pressing the ENTER-key when the text MOVE FUNCTION BLOCK is on the bottom row.

Next you have to enter the task number. Select 1, 2 or 3 with the single arrow-keys and press ENTER-key.

The function block to be moved is selected from the execution order list. Function blocks in the execution order list are shown on the bottom row:

```
MOVE FUNCTION BLOCK  
SELECT FB IN TASK[3]  
2: [INV (34)]
```

2 means the position in the execution order list. On the brackets there is the function block type and instance number. LAST (0) means the end of the execution order list.

Press the ENTER-key when you have the block to be moved on the display.

Next step is to enter the new position of the function block in the execution order list.  
Function blocks in the execution order list are shown on the bottom row:

INV (34)

1: [INV (10)]

Press the ENTER-key when you have the correct position on the display. The function block will be moved before the block shown on the display.

### **Terminate FB programming**

Select this function by pressing the ENTER-key, when you want to exit from the function block programming.

### **Connecting FB inputs**

FB inputs are connected by setting the corresponding pointers.

# Chapter 2 - Function Block Data Sheet

## 2. The Function Block Data Sheets

A Function Block description starts with a short summary that describes the main function of the FB. The graphic symbol of the block is shown above or to the right of the summary.

The type of the block is described under the heading **Call**.

FB pins are described under the heading **Connections**. This section provides a table giving each terminal's name, type and usage.

A detailed functional description is presented under the heading **Function**.

The block instance number and pin numbers are given in the table under the heading **Block numbers and pin addresses**.

The description finishes with a guide for using the function block in the Graphical Application Designer (GAD) engineering tool.

### Data types

The type of the pin is given as xy, where x is I, O or P if it is an input, an output or a parameter terminal, and y denotes the data type described in Table 2.

Table 1 FB pin types

Designation	Pin type	Comment
I	Input:	can be connected
P	Parameter:	can be given a value
O	Output:	output from the FB

Table 2 Data types

Designation	Data type	Range
I	Integer with sign, 16 bit.	(-32768...32767)
U	Integer without sign, 16 bit.	(0...65535)

### Handling of Boolean values

There are a lot of function blocks which handle Boolean input and output values. All logic blocks (e.g. AND, OR etc.) and also many other blocks have Boolean inputs and outputs.

Boolean inputs are following the rule:

- if the value is not equal to 0 ( $\neq 0$ ), it is logical TRUE
- if the value is equal to 0 ( $= 0$ ), it is logical FALSE.

Boolean outputs are following the rule:

- if the output is logical TRUE, the output is set to -1
- if the output is logical FALSE, the output is set to 0.

## Chapter 3 - Function Blocks listed by type

### 3. DCS 500 Function Blocks listed by type

Function Blocks valid for Software Versions:

**21.105, 21.106, 21.107, 21.108, 21.120, 21.121, 21.122, 21.123**

#### Logic blocks

Inverter	INV
Two input OR gate	OR2
Four input OR gate	OR4
Two input AND gate	AND2
Four input AND gate	AND4
Memory block	SR
Memory block with Data input	SR-D
Exclusive OR gate	XOR

#### Arithmetic blocks

Two input Adder	ADD2
Four input Adder	ADD4
Two input Subtraction	SUB2
Two input Multiplier	MUL
Two input Divider	DIV2
Integer Scaling	MULDIV
Absolute Value	ABS

#### Selecting blocks

Minimum Selector	MIN2
Maximum Selector	MAX2
Switch with Changeover	SW-C1
One of four Selector	MUX-I4

#### Timing blocks

Time Delay On	TON
Time Delay Off	TOFF
Retriggerable pulse	MONO
Pulse Counter	COUNT
Oscillator	OSC-B

#### Comparing or limiting blocks

Comparator	COMP-I
Limiter	LIM-N1

#### Control and adjustment blocks

Low-pass Filter	FILT-I
Integrator	INTEG
PI controller	PI-I
Function generator (broken line)	FUNG-1V

**Constant setting and data transfer blocks**

Data transfer, one value	WRITE1
Data transfer, four values	WRITE4
User parameters	PAR
Code Converter, Integer to Binary	CONV-IB
Code Converter, Binary to Integer	CONV-BI
Extract a single bit value	BITGET
Set a single bit value	BITSET

Function Blocks valid for Software Version:  
**21.121**

**Selecting blocks**

Transmit Invert Integer	TRII
-------------------------	------

**Control and adjustment blocks**

Acceleration weighting	ACW
Diameter calculator	DIAC
Derivation with low filter	DT
Loss weighting	LSW
Special controller	SC
Special start logic	SSL
Tension reference	TERE
Torque from tension	TOTE
Velocity reference	VERE
Winder logic	WILO

**Constant setting and data transfer blocks**

Diameter Relation	DIAREL
Parameter of winder	PARW

Function Blocks valid for Software Version:  
**21.122**

**Constant setting and data transfer blocks**

Disable Fault	DISF
User parameters	PARW
Set Fault	SETF

Function Blocks valid for Software Version:  
**21.123**

**Constant setting and data transfer blocks**

Switch parameter and transfer	SW-P-T
-------------------------------	--------

Left free for further extensions

## **Chapter 4 - Function Blocks listed in alphabetic order**

### **4. DCS 500 Function Blocks listed in alphabetic order with short form description**

Function Blocks valid for Software Versions:  
**21.105, 21.106, 21.107, 21.108, 21.120, 21.121, 21.122, 21.123**

<b>ABS</b>	Calculates the absolute value of an integer .
<b>ADD2</b>	Adds two integers.
<b>ADD4</b>	Adds four integers.
<b>AND2</b>	Gives the Boolean product of two Boolean values.
<b>AND4</b>	Gives the Boolean product of four Boolean values.
<b>BITGET</b>	Reads the value of the selected bit from an integer value.
<b>BITSET</b>	Sets the value of the selected bit in an integer value.
<b>COMP-I</b>	Compares two integers.
<b>CONV-BI</b>	Converts data in BC coded Boolean inputs into data in integer format.
<b>CONV-IB</b>	Converts data in integer format into BC coded Boolean variables.
<b>COUNT</b>	Pre-setable counter for counting pulses, up or down. With checking of the value relative to 0.
<b>DIV2</b>	Divides two integers.
<b>FILT-I</b>	Single pole low-pass filter for integer signals.
<b>FUNG-1V</b>	Generates a piece-wise linear function of one variable. Function is described by five (x,y) co-ordinates.
<b>INTEG</b>	Gives integration effect. The block has inputs and outputs for limit values, setting of gain and following an external reference.
<b>INV</b>	Inverts a Boolean value.
<b>LIM-N1</b>	Limits an integer value between high and low limits.
<b>MAX2</b>	Selects the larger of two integers.
<b>MIN2</b>	Selects the smaller of two integers.
<b>MONO</b>	Generates a pulse with a given duration when the input changes from 0 to <> 0. Pulse duration and retriggering are specified with parameters.
<b>MUL2</b>	Multiplies two integer values.
<b>MULDIV</b>	Scaling block for the integer values.
<b>MUX-I4</b>	Selector for 4 inputs. Integer address.
<b>OR2</b>	Gives the Boolean sum of two Boolean values.
<b>OR4</b>	Gives the Boolean sum of four Boolean values.
<b>OSC-B</b>	Oscillator for a Boolean variable with variable frequency and pulse time.
<b>PAR</b>	Defines an user parameter that can be stored in the parameter backup FEPROM.
<b>PI-I</b>	PI controller. The block permits limiting of the output signal and has a follow function.
<b>SR</b>	Memory for Boolean variables. The block has one Set and one Reset input.

*Chapter 4 - Function Blocks listed in alphabetic order*

<b>SR-D</b>	Memory for Boolean variables. The block has one Set and one Reset input and Data and Clock inputs for clocking in data.
<b>SUB2</b>	Subtracts one integer from another.
<b>SW-C1</b>	Switching block with one change-over channel.
<b>TOFF</b>	Delay for turning a Boolean signal off.
<b>TON</b>	Delay for turning a Boolean signal on.
<b>WRITE1</b>	Data transfer of one value from source to destination.
<b>WRITE4</b>	Data transfer of four values.
<b>XOR</b>	Gives the exclusive Boolean sum of two Boolean values.

**Function Blocks valid for Software Version:  
21.121**

<b>ACW</b>	Acceleration weighting
<b>DIAC</b>	Diameter calculator
<b>DT</b>	Derivation with low filter
<b>LSW</b>	Loss Weighting
<b>DIAREL</b>	Parameter for diameter relation
<b>PARW</b>	Parameter for winder application
<b>SC</b>	Special controller
<b>SSL</b>	Special start logic
<b>TERE</b>	Tension reference
<b>TOTE</b>	Torque of tension
<b>TRII</b>	Transmit invert integer
<b>VERE</b>	Velocity reference
<b>WILO</b>	Winder logic

**Function Blocks valid for Software Version:  
21.122**

<b>DISF</b>	Disabled selected fault
<b>PARW</b>	User parameters
<b>SETF</b>	Set selected fault

**Function Blocks valid for Software Version:  
21.123**

<b>SWPT</b>	Switch parameter and transfer
-------------	-------------------------------

## **Chapter 5 - Execution Times and No. of Function Blocks**

### **5. Execution Times and Number of Function Blocks**

Function Blocks valid for Software Versions:  
**21.105, 21.106, 21.107, 21.108, 21.120, 21.121, 21.122, 21.123**

<b>Name</b>	<b>Execution time, typical (<math>\mu</math>s)</b>	<b>Number of blocks</b>
ABS	9	4
ADD2	12	10
ADD4	15	2
AND2	9	40
AND4	12	10
BITGET	12	8
BITSET	17	8
COMP-I	11	10
CONV-BI	70	2
CONV-IB	67	2
COUNT	26	2
DIV2	15	4
FILT-I	27	5
FUNG-1V	37	1
INTEG	51	2
INV	8	25

DSWPT_488 ... _493	52	6

# Chapter 6 - Description of Function Blocks

## Absolute Value

## ABS

### Summary

**ABS** (**ABS**olute value) is used to obtain the absolute value of an integer value.

**Call**    **ABS\_275...ABS\_278**

**Connections**    *Table 1*

Name	Type	Description
I	II	Input for number, whose absolute value is to be obtained.
O	OI	Output for the absolute value of I.

### Function

The absolute value of the input I is stored at the output O.

**Block numbers and pin addresses** *Table 2*

FB number	275	276	277	278
I	2991	2992	2993	2994
O	12776	12777	12778	12779

### Guide for using Function Block in the Graphical Application Designer

Definable attributes :                    *Task number / Execution order, Comment text (several languages), General text (one language)*

# Adder

# ADD

## Summary

ADD (Adder) is used to calculate the sum of integer values.

**Call**    **ADD2\_222...ADD2\_231, ADD4\_238, ADD4\_239**

## Connections Table 1

Name	Type	Description
IN1	II	Input for addend.
IN2	II	Input for addend
IN3	II	Input for addend.
IN4	II	Input for addend.
O	OI	Output for sum.

## Function

The values at inputs IN1...IN4 are added and the sum is stored at output O.

## Overflow

If the maximum positive or negative value is exceeded, the output is limited to the highest or lowest allowable value for the integer data type.

## Block numbers and pin addresses Table 2

### ADD2:

FB number	222	223	224	225	226	227	228	229	230	231
IN1	2909	2911	2913	2915	2917	2919	2921	2923	2925	2927
IN2	2910	2912	2914	2916	2918	2920	2922	2924	2926	2928
O	12742	12743	12744	12745	12746	12747	12748	12479	12750	12751

**ADD4:**

FB number	238	239
IN1	2929	2933
IN2	2930	2934
IN3	2931	2935
IN4	2932	2936
O	12752	12753

# And Gate

# AND

## Summary

AND is used to form a Boolean product of Boolean input values.

**Call**    **AND2\_110...AND2\_149, AND4\_170...AND4\_179**

## Connections Table 1

Name	Type	Description
IN1	II	Input
IN2	II	Input
IN3	II	Input
IN4	II	Input
O	OI	Output

## Function

The output signal is set to -1 if all inputs IN1..IN4 are <> 0. See the truth table below.

## Truth table AND2 Table 2

IN1	IN2	O
= 0	= 0	0
= 0	≠ 0	0
≠ 0	= 0	0
≠ 0	≠ 0	-1

**Block numbers and pin addresses** Table 3**AND2:**

FB number	110	111	112	113	114	115	116	117	118	119
IN1	2727	2729	2731	2733	2735	2737	2739	2741	2743	2745
IN2	2728	2730	2732	2734	2736	2738	2740	2742	2744	2746
O	12666	12667	12668	12669	12670	12671	12672	12673	12674	12675

## Read One Bit

# BITGET

### Summary

**BITGET** block is used to read a selected bit from an integer value. It is used to read packed Boolean status information coming from a communication link or created by the drive.

**Call**    **BITG\_448...BITG\_455**

### Connections    *Table1*

Name	Type	Description	Values
BITNR	II	Input for the selected <b>BIT NumberR</b> to read	0...15
I	II	Input for the packed Boolean data	
O	OI	Status of the selected bit	

### Function

The bit value of the input data I, specified by BITNR, is loaded to the output O. When selected input bit is 0 the output O is 0, and when input bit is 1 then the output is -1. If BITNR is not in the range 0...15 then the output O is set to 0.

### Block numbers and pin addresses    *Table 2*

FB number	448	449	450	451	452	453	454	455

## Set One Bit

## BITSET

## Summary

**BITSET** block is used to set a selected bit of an integer value. It is used when writing status information to a packed Boolean parameter or signal.

Call **BITS\_460...BITS\_467**

Connections *Table 1*

Name	Type	Description	Values
EN	II	<b>EN</b> able. Input for storage of a new value each time the block is executed. If this input is reset (to 0), then the current value of I is loaded unchanged to the output O.	
BITNR	II	Input for selecting the <b>BIT NumberR</b> to set.	0...15
BIT	II	Value of the <b>BIT</b> .	
I	II	Data <b>Input</b> .	
O	OI	<b>Output</b> of the set data.	

## Function

If the value of the input EN is set (to  $\neq 0$ ) then the value of bit number, determined by the input BITNR, of the input data I, is replaced by the value of the input BIT and the result is loaded to the output O.

If the value of EN is reset (to 0) then the value of the input data I is loaded unchanged to the output O.

If the BIT input value is 0 then the selected bit at the output data is 0, and if the BIT input value is  $\neq 0$  then the selected bit at output data is 1.

If BITNR is not in the range 0 to 15 then the output O is set to the value of I. If BITNR is 15 then the value of O will be negative.

## Comparator Integer

## COMP-I

### Summary

**COMP-I** (**COMP**arator - **I**nteger) is used to compare two integers.

**Call**    **COMP\_362...COMP\_371**

**Connections**    *Table 1*

Name	Type	Description
I1	I	Input 1. Input, whose value is compared with the value at input I2
I2	I	Input 2. Input, whose value is compared with the value at input I1
I1>I2	O	Input 1 > Input 2. Output which is set to -1 if the value at input I1 is greater than the value at input I2.
I1=I2	O	Input 1 = Input 2. Output which is set to -1 if the value at input I1 is equal to the value at input I2.
I1<I2	O	Input 1 < Input 2. Output which is set to -1 if the value at input I1 is less than the value at input I2.

### Function

The values at the two inputs are compared and the result of the comparison can be read at the outputs I1<I2, I1=I2 and I1>I2.

At start-up, output I1=I2 is set to -1 before the first execution of the block regardless of the values of inputs I1 and I2.

# Code Converter Binary to Integer

# CONV-BI

### Summary

**CONV-BI (CONVerter-Boolean to Integer)** converts data from BC formed Boolean variables into integers. The block has a memory function for storage of converted data.

**Call** CVBI\_445,..CVBI\_446

**Connections** Table 1

Name	Type	Description
S	II	<b>Set.</b> Input for storage of a new value each time the block is executed. When this input is reset (to 0), the latest calculated value will remain at the outputs
L	II	<b>Load.</b> Dynamic input for loading data.
R	II	<b>Reset.</b> Input for clearing the output. This input overrides S and L inputs.

Name	Type	Description
I1	II	<b>Input 1.</b> Input 1 for BC.
I2	II	<b>Input 2.</b> Input 2 for BC.
I3	II	<b>Input 3.</b> Input 3 for BC.
I4	II	<b>Input 4.</b> Input 4 for BC.
I5	II	<b>Input 5.</b> Input 5 for BC.
I6	II	<b>Input 6.</b> Input 6 for BC.
I7	II	<b>Input 7.</b> Input 7 for BC.
I8	II	<b>Input 8.</b> Input 8 for BC.
I9	II	<b>Input 9.</b> Input 9 for BC.
I10	II	<b>Input 10.</b> Input 10 for BC.
I11	II	<b>Input 11.</b> Input 11 for BC.
I12	II	<b>Input 12.</b> Input 12 for BC.
I13	II	<b>Input 13.</b> Input 13 for BC.
I14	II	<b>Input 14.</b> Input 14 for BC.
I15	II	<b>Input 15.</b> Input 15 for BC.
I16	II	<b>Input 16.</b> Input 16 for BC.
O	OI	<b>Output.</b> Output for converted data.

### Function

The block can convert 16 bit binary code (BC) to integer of data type I (16 bits) .

### Examples of input values with different recordings

Table 2

Input integer value	
Input	BC with sign
I1	1
I2	2
I3	4
I4	8
I5	16
I6	32
I7	64
I8	128
I9	256
.	.
I16	sign

### Storage of data

When input L is set (from 0 to  $\neq 0$ ), the code at inputs I1 to I16 is immediately converted and stored. If input S is set (to  $\neq 0$ ), the input code is converted and the integer is stored each time the block is executed. When S is reset (to 0) after having been set, the data stored most recently remains. The input S overrides the input L, i.e. when S is set (to  $\neq 0$ ), L has no effect.

### Clearing

The input R clears the output and prevents all further storage of data while R is set (to  $\neq 0$ ).

.	.
O16	2 <sup>15</sup>

### Storage of data

When input L is set (from 0 to  $\neq 0$ ), the integer at input I is immediately converted and if input S is set (to  $\neq 0$ ), the integer input is stored each time the block is executed. When S is reset (to 0) after having been set (to  $\neq 0$ ), the data stored most recently remains until the block is executed once more with one of the inputs S, L or R set. The input S overrides the input L, i.e. when S is set (to  $\neq 0$ ), L has no effect.

### Clearing

The input R clears the output to 0 and prevents all further storage of data while R is set (to  $\neq 0$ ).

## Counter

## COUNT

## Summary

**COUNT (COUNTER)** is a presetable counter for counting pulses, up or down. The counter also monitors the relation of the counter value to 0.

**Call** COUN\_358,..COUN\_359

**Connections** Table 1

Name	Type	Description
L	II	<b>Load.</b> Loads the counter with the value at input I
U/D-N	II	<b>Up/Down-N.</b> Input which determines if the counter is to count up (U/D-N $\neq$ 0) or down (U/D-N = 0)
C	II	<b>Clock.</b> When this input changes from 0 to $\neq$ 0 the counter counts up or down in accordance with the status of the input U/D-N.
R	II	<b>Reset.</b> Input which clears the counter and prevents all further counting or loading. <b>This input overrides all other inputs!</b>
EN	II	<b>ENable.</b> Input which is set to $\neq$ 0 to permit counting or loading. Reset execution is, however, performed independently of EN.
I	II	<b>Input.</b> Input for new value when loading.
>0	OI	Output which is set to -1 when the value of the counter is greater than 0.
=0	OI	Output which is set to -1 when the value of the counter is 0.
<0	OI	Output which is set to -1 when the value of the counter is less than 0.
O	OI	<b>Output.</b> Output for counter value.

## Function

When input C is set, the counter value immediately increases or decreases. The value increases if U/D-N  $\neq$  0 and decreases if U/D-N = 0. The duration of the counter period cannot be less than 2 \* the cycle time of the program.

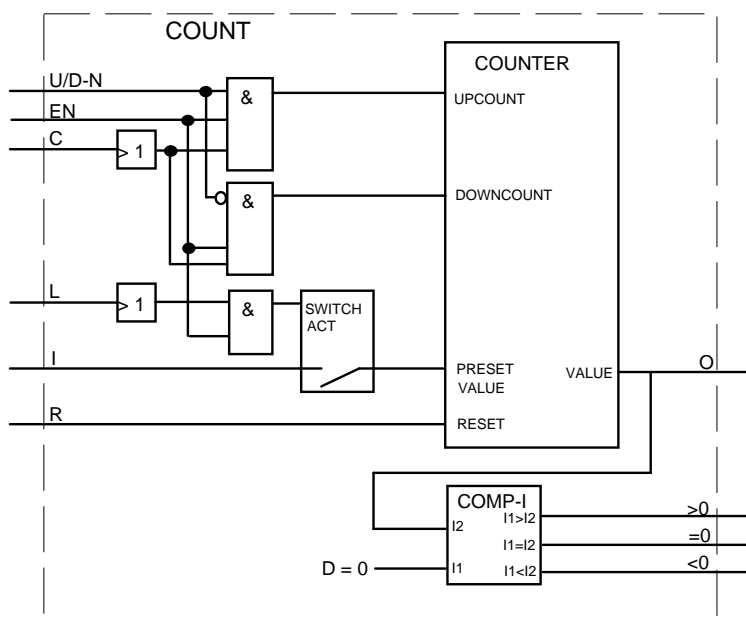

When the input L is set to  $\neq$  0, the counter is loaded with the value at input I. If both input L and C are set to  $\neq$  0 simultaneously, the counter is first loaded after which an up or down count is performed. The input EN must be set to  $\neq$  0 for the counter to count or load a new value.

### Clearing

The input R clears the counter and prevents all further counting or loading. R overrides EN.

### Supervision

The status outputs specify the relation of the counter value to zero (> 0, = 0, < 0). When the counter reaches its least or greatest value for the data type, all counting ceases.

# Filter Integer

# FILT-I

## Summary

FILT-er Integer block is used as a single pole low pass filter for integer values.

## Call `FILT_383...FILT_387`

## Connections Table 1

Name	Type	Description	Values
I	II	Input.	
T1	PI	Parameter. Filter time constant 1=1ms.	0...32767 [ms]
O	OI	Output. Filtered value.	

## Function

The step response in the time plane for a single low pass filter is:

$$O(t) = I(t)(1 - e^{-t/T1})$$

The transfer function for a single low pass filter is:

$$G(s) = 1/(1 + sT1)$$

The filtering algorithm is calculated using the following formula:

$$O_n = \frac{I_n + (T1/TS) \times O_{n-1}}{T1/TS + 1}$$

Where TS is the cycle time of the block in milliseconds and  $O_{n-1}$  is the output from the previous execution cycle. If  $T1/TS < 1$  then the output O is equal to the input I. Internal calculation of the algorithm is done with 32-bit accuracy to avoid offset errors.

## Block numbers and pin addresses Table 2

# Function Generator

# FUNG-1V

## Summary

**FUNG-1V (FUNction Generator 1 Variable)** is used for generation of an user defined function of one variable,  $y = f(x)$ . The function is defined by 5 (x,y) co-ordinates. Linear interpolation is used for values between these co-ordinates.

## Call FUNG\_396

**Connections** Table 1

Name	Type	Description
X	II	<b>X</b> -value. Input for X-value.
BAL	II	<b>BAL</b> ance. Input for activation of balancing.
BALREF	II	<b>BAL</b> ance <b>REF</b> erence. Value which the Y-output is to adopt with balancing.
X1	PI	Co-ordinate 1 on X-axis.
Y1	PI	Co-ordinate 1 on Y-axis.
X2	PI	Co-ordinate 2 on X-axis.
Y2	PI	Co-ordinate 2 on Y-axis.
X3	PI	Co-ordinate 3 on X-axis.
Y3	PI	Co-ordinate 3 on Y-axis.
X4	PI	Co-ordinate 4 on X-axis.
Y4	PI	Co-ordinate 4 on Y-axis.

Name	Type	Description
X5	PI	Co-ordinate 5 on X-axis.
Y5	PI	Co-ordinate 5 on Y-axis.
Y	OI	<b>Y</b> -value. Output for Y-value.
ERR	OI	<b>ERR</b> or. Output set (to -1) if X outside the value of XTAB or if Y, on balancing, is outside the YTAB values.
BALREFO	OI	<b>BAL</b> ance <b>REF</b> erence <b>O</b> utput. Output for calculated X-value with balancing.

## Function

The function generator FUNG-1V for one variable calculates an output signal Y for a value at the input X. The calculation is performed in accordance with a piece by piece linear function which is determined by the inputs X1,Y1...X5,Y5. For each X-value, there is a corresponding Y-value. The Y-value at the output is calculated by means of linear interpolation between the two X-values which are the next lower and higher values for the input value X. The values X1...X5 must be in ascending order.

## Interpolation

The function generated is performed as follows:

$$y = y_k + (x - x_k) * (y_{k+1} - y_k) / (x_{k+1} - x_k)$$

## Balancing

If BAL is set to  $\neq 0$ , the value at Y is set to the value of the input BALREF. The X-value which corresponds to this Y-value is obtained at the output BALREFO. On balancing, the X-value is calculated by interpolation in the same way the Y-value is calculated during normal operation. If balancing is used, the values Y1...Y5 must be in ascending or descending order.

## Error Signal

If the input signal X is outside the range defined by X1...X5, the ERR output is set to -1. The Y-value is then set to Y5 or Y1 value depending on value of X.

ERR is also set to -1 if BALREF is outside the Y1...Y5 value range when BAL is set to  $\neq 0$ . The value at Y is then set to the value at the input BALREF and BALREFO is set to X5 or X1 value depending on value of BALREF.

# Integrator

# INT

## Summary

**INT (INTegrator)** is used to give an integration effect. The output signal can be limited with limit values specified with parameters. The balancing function permits the output signal to track an external reference and permits a bumpless return to the normal function.

**Call** INT\_391,..INT\_392

**Connections** Table 1

Name	Type	Description
I	II	Input. Input for actual value.
K	PI	Parameter for setting proportional gain. 100 = gain=1.
TI	PI	Time Integration. Parameter for time constant for integration. 1 = 1ms.
RINT	II	Reset <b>INT</b> egrator. Input for clearing the integrator.
BAL	II	<b>BAL</b> ance. Input for activation of tracking
BALREF	II	<b>BAL</b> ance <b>REF</b> erence. Input for reference value when tracking.
OHL	PI	<b>Output High Limit</b> . Parameter for upper limit value.
OLL	PI	<b>Output Low Limit</b> . Parameter for lower limit value.
O	OI	<b>Output</b> . Output signal.
O=HL	OI	<b>Output = High Limit</b> . Output which is set to -1 if the output reaches the higher limit value.
O=LL	OI	<b>Output = Low Limit</b> . Output which is set to -1 if the output reaches the lower limit value.
ERR	OI	<b>ERR</b> or. Set to -1 if OHL is less than OLL

## Function

The INT function can be written in the time plane as:

$$O(t) = K/TI(\int I(t)dt)$$

The main property when controlling is that the output signal retains its value when the input signal  $I(t) = 0$ .

The step response in the time plane is

$$O(t) = k \cdot I(t) \cdot t / T1.$$

The transfer function for an integrator is:

$$G(s) = K(1/sTI).$$

## Gain, Integration Time Constant and Sampling Time

The constant  $K \cdot TS / TI$  is calculated in advance to reduce the execution time of the block to a minimum. The result is stored internally in the block. This constant is calculated again if  $T1$  or  $K$  has changed, or if the sampling time  $TS$  has changed. When calculating, a test is performed to check whether  $TS/T1 < 1$ . In this case  $TS/T1$  is set equal to 1.

## Clearing of Integrator

The algorithm is cleared when  $RINT$  goes to  $\neq 0$ .

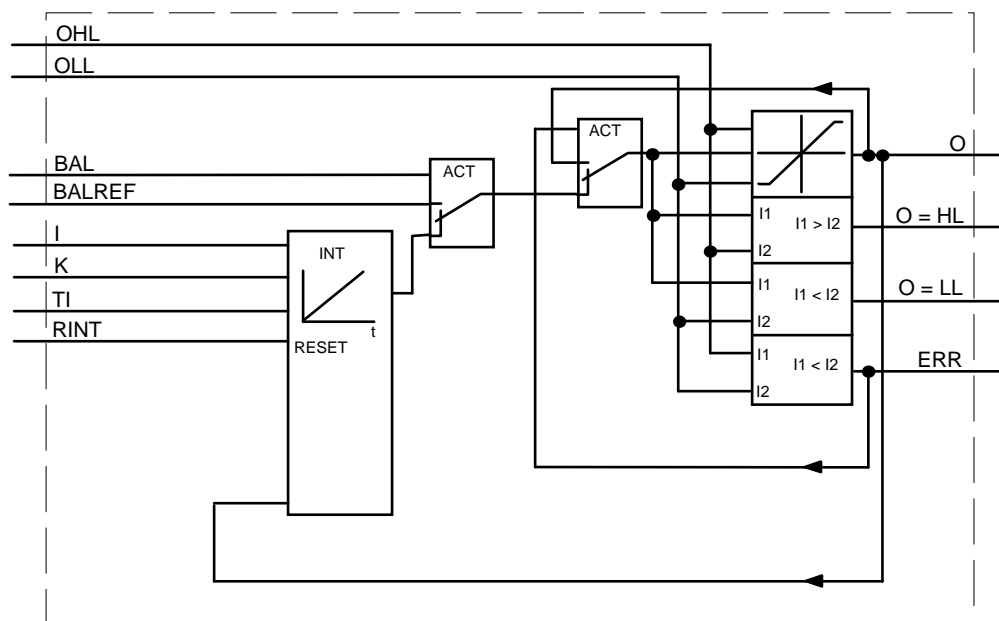

## Tracking

If  $BAL$  is set to  $\neq 0$ , the integrator immediately goes into tracking and the output  $O$  is set to the value of the input  $BALREF$ . If the value at  $BALREF$  exceeds the output signal limits, the output is set to the applicable limit value. On return to the normal function, the value of output  $O$  during the previous execution cycle in tracking mode is kept for one cycle, after which integration will be performed for this value.

## Limitation Function

The limitation function limits the output signal to the values at the inputs  $OHL$  for upper limit and  $OLL$  for the lower limit. If the actual value exceeds the upper limit, the output  $O = HL$  is set to -1. If it falls below the lower limit, the output  $O = LL$  is set to -1. The block checks that the upper limit value  $OHL$  is greater than the lower limit value  $OLL$ . If not, the output  $ERR$  is set to -1. While the error status persists, the outputs  $O = HL$ ,  $O = LL$  and  $O$  retain the values they had in the previous execution cycle before the error occurred. After limitation or error status, normal integration is performed from the current value.

# Inverter

# INV

## Summary

INV is used for inverting Boolean variables.

**Call** INV\_010...INV\_034

**Connections** Table 1

Name	Type	Description
IN	II	Input.
O	OI	Output of inverted input value.

## Function

The output signal from the INV block is set (to -1) if the input signal to the block is 0, and reset (to0) when the input signal is  $\neq 0$ . See the truth table below.

# Limitter

# LIM-N

## Summary

**LIM-N** (**LIM**iter - 1 of - **N** address) is used for limitation of integer values.

**Call**    **LIMN\_375...LIMN\_379**

## Connections Table 1

Name	Type	Description
A1	II	<b>Address 1.</b> Input which, when set to $\neq 0$ , limits the output O to the limit values defined by the parameters HLA1 and HLL1.
I	II	<b>Input.</b> Input which is connected to the signal being limited.
HLA1	PI	<b>High Limit Address 1.</b> Parameter for upper limit value which limits the signal when the input A1 is set to $\neq 0$ .
LLA1	PI	<b>Low Limit Address 1.</b> Parameter for lower limit value which limits the signal when the input A1 is set to $\neq 0$ .
ERR	OI	<b>ERRor.</b> Output which is set to -1 when the limit for high level is less than the limit for low level.
O	OI	<b>Output.</b> Output for the limited signal.
I>HLA	OI	<b>Input &gt; High Limit Address.</b> Output which is set to -1 when the upper limit of the block is reached.
I<LLA	OI	<b>Input &gt; Low Limit Address.</b> Output which is set to -1 when the lower limit of the block is reached.

## Function

LIM-N is used to limit a signal with given limits. Boolean output signals indicate when the output is limited.

## Selection of Limit Value

The limit value parameters HLA1 and LLA1 are activated with the input A1. If the input A1 is  $\neq 0$ , the output is limited by HLA1 and LLA1. If A1 is 0, output O is limited to the data value 0.

### Limiting

When the input I exceeds the selected limit, the output O is limited to the limit value. One of the outputs I > HLA or I < LLA will then be set to -1 depending on which limit was exceeded.

### Supervision of Limit Values

The block checks that the limit value HLA1 is greater than the limit LLA1. If HLA1 is less than LLA1, the error signal output ERR is set to -1. The output O and the limit value outputs I > HLA and I < LLA are retained from the previous execution cycle before the error status developed.

# MAX

## Maximum Selector

### Summary

**MAX** (**MAX**imum selector) is used to select the highest of two integer values.

**Call**    **MAX2\_289...MAX2\_293**

**Connections**    *Table 1*

No	Name	Type	Description
IA1	II		Input Address 1. Input which is compared with the IA2 input
IA2	II		Input Address 2. Input which is compared with the IA1 input
O	OI		Output. Output for the highest value.
A	OI		Address. Output for the number of the input having the highest value.

### Function

The values at the inputs IA1 and IA2 are compared and the greatest value is copied to the output O. The number of the input with the highest value is written to the output A. If the two highest signal values are equal when the block is executed for the first time, the signal with the lowest connection number will be the highest.

**Block numbers and pin addresses** *Table 2*

# Minimum Selector

# MIN

## Summary

**MIN** (**MIN**imum selector) is used to select the lowest of two integer values.

**Call**    **MIN2\_281...MIN2\_285**

## Connections *Table 1*

Name	Type	Description
IA1	II	Input Address 1. Input which is compared with the IA2 input
IA2	II	Input Address 2. Input which is compared with the IA1 input
O	OI	Output. Output for the lowest value.
A	OI	Address. Output for the number of the input having the lowest value.

## Function

The values at the inputs IA1 and IA2 are compared and the lowest value is copied to the output O. The number of the input with the lowest value is written to the output A. If the two lowest signal values are equal when the block is executed for the first time, the signal with the lowest connection number will be the lowest.

## Block numbers and pin addresses *Table 2*

# Mono Function

# MONO

## Summary

**MONO** function block can be used e.g. for time limitation of output operation and for automatic functions. The block can also be used for impulse extension, stall alarm generation, etc.

**Call MONO\_350...MONO\_354**

## Connections Table 1

Name	Type	Description
RTG	PI	<b>Re TrigG.</b> Parameter to select whether or not the MONO function is retriggerable. If RTG is set to $\neq 0$ , the retriggerable mode is selected.
I	II	<b>Input.</b> Input which starts the MONO function when the input value changes from 0 to $\neq 0$ .
TP	PI	<b>Time Pulse.</b> Parameter for setting of the pulse time. 1 = 10ms. Max. 650s
O	OI	<b>Output.</b> Output which is set when the MONO function starts and reset when the time set TP has elapsed.
TE	OI	<b>Time Elapsed.</b> Output for time elapsed when output O is set. When the time set TP has elapsed TE will stop. 1 = 10ms.

## Function

A memory is set when the input I is set. The output then goes to -1. When the time set in the timer has elapsed, the memory is cleared and the output O goes to 0.

### MONO function, Not Retriggerable

If the parameter RTG is set to 0, the MONO function is not retriggerable. If a new pulse occurs at the input I before the timer has elapsed, it does not affect the timer. Only when the time set has elapsed and the output O is 0, the MONO function can be restarted by the input value I going from 0 to  $\neq 0$ .

### MONO function, Retriggerable

If the parameter RTG is set to  $\neq 0$ , the MONO function is retriggerable. I.e. the timer starts from 0 each time a new pulse occurs at the input I. If a new pulse occurs at the input I before the timer has elapsed, the timer will restart from zero.

# Multiplier

# MUL

## Summary

**MUL** (**MUL**tiplier) is used for multiplication of two integer values.

**Call**    **MUL2\_247...MUL2\_250**

## Connections Table 1

Name	Type	Description
IN1	II	Input for multiplicand.
IN2	II	Input for multiplier
O	OI	Output for product.

## Function

The values at the inputs IN1 and IN2 are multiplied and the product is stored to the output O.

## Overflow

If the maximum positive or negative value is exceeded, the output is limited to the highest or lowest allowable value for the integer data type.

## Block numbers and pin addresses Table 2

## Integer Scaling Block

# MULDIV

### Summary

**MULT**plier **DIV**ider block is used to scale integer values by multiplying the input value with a fractional number.

**Call**    **MULD\_260...MULD\_269**

**Connections**    *Table 1*

Name	Type	Description
I	II	Input for multiplicand
MUL	II	Input for <b>MULT</b> plier.
DIV	II	Input for <b>DIV</b> isor
O	OI	<b>Output</b> for quotient.

### Function

The product of input I and input MUL is divided by the input DIV. The quotient is loaded to the output O. The block uses internally 32 bit accuracy to perform the multiplication.

### Overflow

If the maximum positive value is exceeded, the output O is limited to +32767. If the minimum negative value is exceeded, the output O is limited to -32768.

**Block numbers and pin addresses** *Table 2*

## Multiplexer with Integer Address

## MUX-I

### Summary

MUX-I (MULTipleXer - with Integer address) is used as a selector.

Call **MUX4\_312...MUX4\_313**

### Connections *Table 1*

Name	Type	Description
A	II	<b>Address.</b> Input for address value which specifies which input is to be connected to the output O. When A = 0, the output is set to 0.
IA1	II	<b>Input Address 1.</b> Input number 1 to the selector.
IA2	II	<b>Input Address 2.</b> Input number 2 to the selector.
IA3	II	<b>Input Address 3.</b> Input number 3 to the selector.
IA4	II	<b>Input Address 4.</b> Input number 4 to the selector.
AERR	OI	<b>Address ERROR.</b> Output which is set to -1 when the address value is greater than the number of inputs, or negative.
O	OI	<b>Output.</b> Data output from the selector.

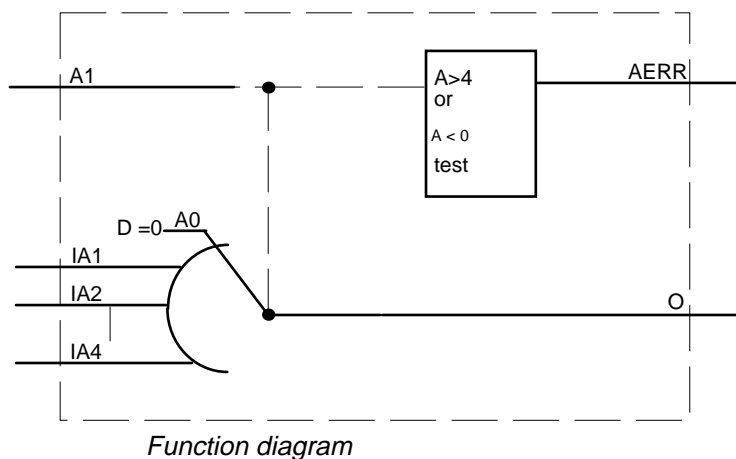

### Function

#### Addressing

The input data value (IA1...IA4) connected to the output O is selected with an address (1...4) in the input A. If the address is 0, the data value 0 is written to the output O.

#### Supervision

The address A is monitored and if its value is greater than the number of inputs or negative, the error signal output AERR is set. The data value 0 is then written to the output.

# Oscillator Boolean Variables

# OSC-B

## Summary

**OSC-B (OSCillator - Boolean variables)** with variable frequency and pulse time. OSC-B is used when pulse trains with period from 2 \* cycle time up to 650 sec are needed.

**Call OSCB\_361**

**Connections** Table 1

Name	Type	Description
EN	II	<b>EN</b> able. Input for starting the oscillator.
TP	PI	<b>Time Pulse</b> . Parameter for setting the pulse time. 1 == 10ms.
TC	PI	<b>Time Cycle</b> . Parameter for setting the period. The period must be greater than the pulse duration. 1 == 10ms. Max. 650s.
O	OI	<b>Output</b> . Oscillator output.

## Function

The oscillator starts when the input EN is set (to ≠ 0). Figure 2. shows an example of an oscillator time diagram.

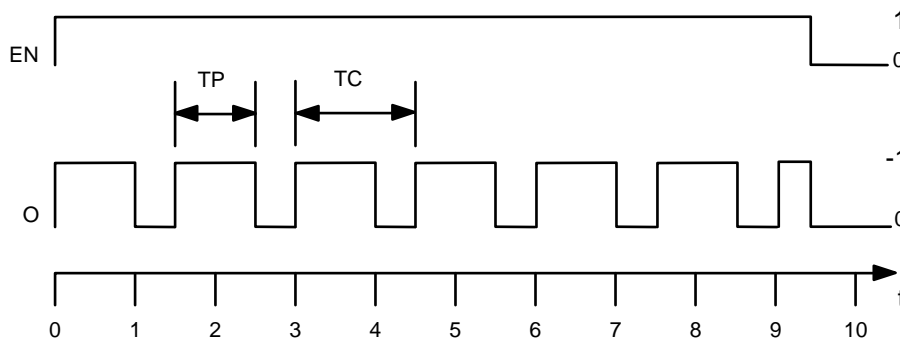

Figure 2. Example of time diagram with TP = 1 s and TC = 1.5 s

## PI-function Integer Values

## PI-I

### Summary

**PI-I** (Proportional Integrating regulator with Integer calculation) is used as a PI-regulator for serial compensation in the closed loop control system. Control deviation is the input signal for the controller. The output signal can be limited to limits specified by input parameters. The tracking function forces the output signal to follow an external reference. The transfer from tracking to normal function with PI algorithm is bumpless.

### Call **PI-I\_394**

### Connections *Table 1*

Name	Type	Description	Values
I	II	Input. Input for deviation value.	-32768..32767
K	PI	Parameter for setting gain.	0..32767(%)
TI	PI	Time Integration. Parameter for integration time constant.	0..32767(ms)
RESET	II	<b>RESET</b> the regulator outputs OPI and O to "0".	
BAL	II	<b>BAL</b> ance. Input for activation of tracking.	
BALREF	II	<b>BAL</b> ance <b>REF</b> erence. Input for reference value when tracking.	-32768..32767
OHL	PI	<b>Output High Limit</b> . Parameter for upper limit value.	-32768..32767
OLL	PI	<b>Output Low Limit</b> . Parameter for lower limit value.	-32768..32767
O	OI	<b>Output</b> . Output signal.	-32768..32767
O = HL	OI	<b>Output = High Limit</b> . Output which is set to -1 if the output reaches to the higher limit value	
O = LL	OI	<b>Output = Low Limit</b> . Output which is set to -1 if the output reaches to the lower limit value	
ERR	OI	<b>ERR</b> or. Output which is set to -1 if OHL is less than OLL.	
OPI	OI	<b>Output of PI</b> regulator before limitation.	-32768..32767

## Gain and Integration Time Constant calibration

The calibration of the Proportional Gain **K** is in "%". It means that value  $K = 100$  corresponds to a multiplication factor of 1.0 (100%). The calibration of the Integration Time Constant **TI** is directly in milliseconds.

## Transfer Function

P and I parts of the controller are calculated independently.

The PI function can be written in the time plane as:

$$O(t) = K * [I(t) + \frac{1}{TI} * \int I(t) * dt]$$

The transfer function of the PI controller is:

$$G(s) = K * [1 + \frac{1}{s * TI}]$$

This has been implemented in the PI-I block with a recursive algorithm. The basic form of this algorithm is:

1.  $INT(k) = INT(k-1) + K * I(k) * \frac{TS}{TI}$
2.  $O(k) = K * I(k) + INT(k)$

where:      TS is an execution interval of the controller.  
              INT is the integral component

## Clearing the Regulator Output

When the RESET input signal is set to  $\neq 0$  the output of controller is set to 0. The Integrator part of regulator can be cleared by setting input TI to 0. When TI is set again to a value  $\neq 0$ , the transfer to normal operation is bumpless.

## Limitation Function

The OLL and OHL parameters provide the minimum and maximum limit values for the controller output signal. If the actual value exceeds the maximum limit value, then the output "O=HL" is set to -1 and if it falls below the minimum limit value, then the output "O=LL" is set to -1. The block also compares OHL with OLL. If OLL value is greater than OHL, then the ERR output is set to -1. While the error status persists, the output limits "O=HL", "O=LL" retain their previous values.

## Tracking

When BAL input is set to  $\neq 0$ , the regulator output "O" is forced to follow the reference value from the BALREF input. If the BALREF signal exceeds the output limits, the output is set to the applicable limit value.

## Bumpless transfer between Tracking and Normal Mode

The transfer from **Tracking** mode is bumpless. This is achieved by internal re-calculation of the integration part in the tracking mode according to:

$$INT(k) = O(k) - K * I(k)$$

There is no explicit feature in the regulator to support directly the bumpless transfer to the Tracking mode. However, such function can be easily implemented, by using other function blocks to connect the output "O" of the controller to its BALREF input.

# Memory Block

# SR

## Summary

The memory block **SR** (Set Reset memory) is used as a memory for Boolean variables.

**Call** SR\_185...SR\_194

**Connections** Table 1

Name	Type	Description
S	II	Set input
R	II	Reset input which overrides the set input.
O	OI	Output from the memory block.

## Function

The block output is set (to -1) if the set input is set (to  $\neq 0$ ) while the reset input is reset (to 0). If the reset input is set (to  $\neq 0$ ), the output is unconditionally reset (to 0).

## Memory Block with Data Input

## SR-D

### Summary

The memory block **SR-D** (Set Reset memory - Data input) is used as a memory for Boolean variables.

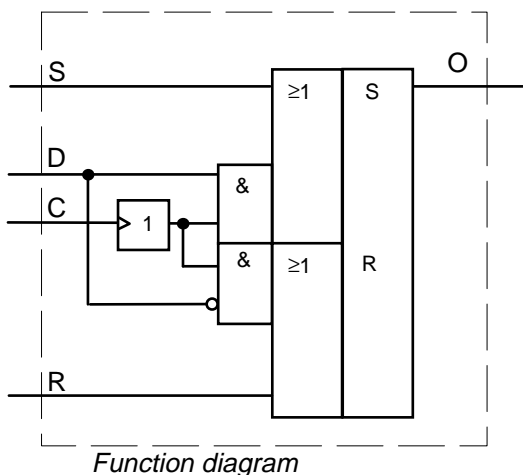

**Call** SR-D\_200...SR-D\_204

### Connections Table 1

Name	Type	Description
S	II	<b>S</b> et input
D	II	<b>D</b> ata input
C	II	<b>C</b> lock. Dynamic input for entry of data from the D input.
R	II	<b>R</b> eset input which overrides the set input.
O	OI	Output from the memory block.

### Function

If only the S and R inputs are used, SR-D functions as an ordinary SR block. When the input R is reset (to 0) and the input C goes to  $\neq 0$ , the value at the input D is stored at the output O. If D is  $\neq 0$ , the output is set to 1. Otherwise output is 0. When the input R is set (to  $\neq 0$ ), the output O is unconditionally reset, i.e. R overrides the other inputs.

# Subtractor

# SUB

## Summary

**SUB** is used for subtraction of two integer values.

**Call**    **SUB2\_241...SUB2\_244**

## Connections Table 1

Name	Type	Description
IN1	II	Input for minuend.
IN2	II	Input for subtrahend.
O	OI	Output for difference.

## Function

The value at input IN2 is subtracted from value at input IN1 and the result is stored at output O.

## Overflow

If the maximum positive or negative value is exceeded, the output is limited to the highest or lowest allowable value for the integer data type.

# Switch with Changeover

# SW-C

## Summary

**SW-C1 (SWitch - Changeover)** is used as a connection block for data and has one channel with closing function.

**Call** SWC1\_297...SWC1\_311

**Connections** Table 1

Name	Type	Description
ACT	II	<b>ACT</b> ivate. Input for activation of the switch. When the input is set to $\neq 0$ the switch is activated.
IN1	II	Input to channel 1 which is connected to the output O when the switch is activated.
IN2	II	Input to channel 1 which is connected to the output O when the switch is not activated.
O	OI	Output.

## Function

When the control input ACT is 0, the data from the input IN2 is connected to the output O. When ACT is set (to  $\neq 0$ ), data comes from the input IN1.

**Block numbers and pin addresses** Table 2

# Time Delay Off

# TOFF

## Summary

Time delay off TOFF (Timer OFF-delay) is used for Boolean off state delay.

## Call TOFF\_337...TOFF\_346

## Connections *Table 1*

Name	Type	Description
I	II	Input for start of time delay.
TD	PI	Time Delay. Parameter for pre-set time. 1 == 10ms. Max. 650s.
O	OI	Output. Output which is reset when the time has elapsed.
TE	OI	Time Elapsed. Output which specifies how long I has been reset. When the pre-set time (TD) has elapsed, TE stops. 1 == 10ms.

## Function

The input signal in the input I is copied with delay to the output O when the input signal changes from ≠ 0 to 0 in accordance with the time pulse diagram in figure 2. The output signal returns to -1, when the input signal changes from 0 to ≠ 0.

Figure 2. Example of time diagram for TOFF with preset time 3s.

## Data Transfer

# WRITE

### Summary

WRITE function block performs data transfer from source to destination.

**Call**    **WRI1\_397...WRI1\_406; WRI4\_411, WRI4\_412**

### Connections Table 1

Name	Type	Description
EN	II	Enable data transfer.
IN1	PI	Source address 1
OUT1	PI	Destination address 1
IN2	PI	Source address 2
OUT2	PI	Destination address 2
IN3	PI	Source address 3
OUT3	PI	Destination address 3
IN4	PI	Source address 4
OUT4	PI	Destination address 4

### Function

If EN ≠ 0 the value of a parameter or a signal indicated by the source address is written to the parameter or signal indicated by the destination address. When EN = 0, no data transfer occurs.

**Block numbers and pin addresses**      *Table 2*

# Acceleration weighting

# ACW

## Summary

**ACW** The function block **AC**celeration **W**eighting is used to calculate the torque of inertia. The input is the acceleration value. The weighting depends of the nominal current of the unit.

**Call** ACW\_473

**Connections**      *Table 1*

Name	Type	Description
DV-IN	II	Input of the acceleration value
SWLEV	PI	Value for the switching hysteresis
WEI-MP	PI	Adjusting value : weighting of the moment of the mechanical inertia (positive acceleration)
WEI-MN	PI	Adjusting value : weighting of the moment of the mechanical inertia (negative acceleration)
WEI-RP	PI	Adjusting value : weighting of the moment of the roll inertia (positive acceleration)
WEI-RN	PI	Adjusting value : weighting of the moment of the roll inertia (negative acceleration)
WEWI	PI	Value of material web width
CALCDIA		Calculated diameter (output of DIAC_468)
DIAREL		Diameter relation (output of PARW_500)
INLEV	OI	Output signal of the switching hysteresis
METORQ	OI	Moment of the mechanical inertia torque
ROTORQ	OI	Moment of the roll inertia torque
ACCTRQ	OI	Total of the inertia torque

## Function

The acceleration value is to create with a maximal value of 20000 for the minimum accelerating and decelerating time. It is better to make this value outside of the DCS, but it is also possible to do this with the function block DERIVATION WITH LOW FILTER (DT) and a MULTIPLIER (MUL).

Two binary signals are created with the acceleration value. The parameter P1 (SWLEV) is used to set the comparator level.

- The output INLEV get high (-1), if the amount of the acceleration level is lower than the value of P1.
- The second signal described the polarity of the acceleration signal (lower than minus P1) and is used to switch the adjusting parameters.

Parameters P2 (WEI-MP) and P3 (WEI-MN) serve for presetting the acceleration share of the complete mechanical equipment of the winder (incl. core). The parameter P2 is used for defining the positive acceleration share, parameter P3 for defining the negative acceleration share (deceleration). The thus adjusted current is attained at minimum diameter.

$$\text{METORQ} = \text{DV}_{\text{IN}} * \frac{(\text{P2 or P3})}{5000} * \frac{\text{DIAREL}}{\text{CALCDIA}}$$

Parameters P4 (WEI-PP) and P5 (WEI-PN) serve for presetting the acceleration share of the material roll. Parameter P4 is used for defining the positive acceleration share, parameter P5 for defining the negative acceleration share (deceleration).

Parameter P6 (WEWI) serves for presetting the web width as percentage value, which is taken into account for acceleration of the material roll. The value adjusted for acceleration is attained at maximum diameter and maximum web width (20000).

$$\text{ROTORQ} = \text{DV}_{\text{IN}} * \frac{(\text{P4 or P5})}{5000} * \frac{\text{WEWI}}{20000} * \frac{\text{DIA}_{\text{max}}}{\text{CALCDIA}} * \frac{\text{CALCDIA}_z^4 - \text{DIAREL}_z^4}{\text{DIA}_{\text{max}_z^4} - \text{DIAREL}_z^4}$$

where

$$\text{DIA}_{\text{max}} = 4000$$

$$\text{DIA}_{\text{max}_z^4} = (4000^2/347)^2$$

$$\text{CALCDIA}_z^4 = (\text{CALCDIA}^2/347)^2$$

$$\text{DIAREL}_z^4 = (\text{DIAREL}^2/347)^2$$

The sum of both torque values is given to the output ACCTRQ.

**Block numbers and pin addresses** *Table 2*

# Diameter calculator

# DIAC

## Summary

**DIAC** The **DI**Ameter **C**alculator is used to integrate the diameter from two inputs. The output is the relation of the minimal and maximal actual diameter.

**Call** DIAC\_468

**Connections**      *Table 1*

Name	Type	Description
VELACT	II	Input actual velocity reference
SPEACT	II	Input actual motor speed
SIGREW	II	Signal rewinder changing lower and upper limits
LIMWR	PI	Limit of the wrong calculation direction
LIMRI	PI	Limit of the right calculation direction
TN	PI	Integrating time
TDEDIA	PI	Integrating time is depended of the diameter ( $T = f(d)$ )
LEVSP	PI	Value of the motor speed to release the calculation
LEVVEL	PI	Value of the velocity to release the calculation
STOP	II	Signal to stop the calculation
SET	II	Signal to set the calculation
SETVAL	II	Value for the setting function
CALCDIA	OI	Output of the calculated diameter
UPLIM	OI	Signal : Output is at the upper limit (4000 dec.)
LWLIM	OI	Signal : Output is at the lower limit (DIAREL)

## Function

The diameter is calculated on the basis of the weighted velocity value, of the speed feedback value and the diameter relation DIAREL (PARW\_500). To avoid jumps, the calculated diameter signal is passed through integrator. The time constant is adjusted by using parameter P3 (TN). Parameter P4 (TEDEDIA) serves for selecting whether this time constant also is to be weighted in dependence on the diameter (advisable in the case of a higher diameter relation).

The differential signal (diameter reference/feedback difference) is additionally provided with two direction-dependent limit values. The value assigned to parameter P1 (LIMWR) effects - irrespective of upwinder or unwinder operation - limitation of the wrong direction of calculation. The proper direction of calculation is limited with the aid of parameter P2 (LIMRI).

Example : The upwinder's increase (increase in diameter) and the unwinder's decrease (decrease in diameter) are limited through parameter P2.

Upon stopping of the diameter calculator, the currently present value is frozen and can only be overwritten via command "Diameter setting" (SET) or by switching off the electronics section.

Any of the following functions suffices to stop the calculator :

- Input STOP (= -1)
- Motor speed lower than the threshold adjusted with parameter [159]
- Velocity reference lower than the threshold adjusted with parameter [154]

**Block numbers and pin addresses** Table 2

FB number	468		Scaling factor	Range of values		Default	Unit

### Guide for using Function Block in the Graphical Application Designer

Definable attributes : *Task number / Execution order, Comment text (several languages), General text (one language)*

# Diameter Relation

# DIAREL

## Summary

The block **DIAREL** is fixed for the using as the **DI**Ameter **REL**ation. This parameter is used by several other winder blocks like DIAC\_468 ... .

This block is not included in execution order list of Task1, Task2 or Task3

## Call **DIAREL**

### Connections *Table 1*

Name	Type	Description
VALUE	II	User defined parameter
O	OI	Output value of the parameter

## Function

The maximal diameter has the internal value of 4000. The minimum and the maximum diameter of the application is needed to calculate this value :

$$DIAREL = 4000 * \frac{\text{min. diameter}}{\text{max. diameter}}$$

Example : With a minimum diameter of 100 mm and a maximum diameter of 1000 mm the value of 400 has to be set into this parameter.

### Block numbers and pin addresses *Table 2*

FB number	500	Scaling factor	Range of values		Default	Unit
			max.	min.		
DIAREL	3701		100	4000	2800	

## Guide for using Function Block in the Graphical Application Designer

Definable attributes : *Task number Comment text (several languages), General text (one language)*

## Derivation with low filter

### Summary

The DT block is used as a derivation block with a low pass filter.

**Call** DT\_480, DT\_481

**Connections** Table 1

Name	Type	Description
I	II	Input for analogue signals
Tn/Tz	PI	Parameter for filter
K	PI	Parameter for amplification
O	OI	Output of the derivation

### Function

The input of the last task will be subtracted from the actual input. This difference is multiplied with the constant K (P2). The result passed through the low pass filter with the time P1.

# Loss weighting

# LSW

## Summary

The current of the loss depending of the diameter are calculated and are added up with function block **LosS Weighting**.

**Call**                    **LSW\_470**

**Connections**        *Table 1*

Name	Type	Description
IN	II	Value of the constant and the current depending of the speed
SET_M2	II	Input switching MUL1 and MUL2
MUL1	PI	Weighting with SET_M2 = 0
MUL2	PI	Weighting with SET_M2 = -1
CALCDIA		Calculated diameter (fixed parameter)
DIAREL		Diameter relation (fixed parameter)
4000		Maximally diameter (Constant 4000)
OUT	OI	Sum of the current value

## Function

The constant and speed-dependent loss values can to give to the input IN.

The diameter-dependent loss value is entered by using parameter P1 (MUL1) or P2 (MUL2). The preset value corresponds with the unit current at maximum diameter.

**Block numbers and pin addresses** Table 2

FB number	470		Scaling factor	Range of values		Default	Unit

# Special controller

## Summary

The **Special Controller** is used as a PI-regulator with a second P for serial compensation in the closed loop control system. The output is limited with an external value and is weighted with a parameter.

## Call SC\_472

### Connections *Table 1*

Name	Type	Description
SCREF	II	Reference value
SCACT	II	Actually value
K1	PI	Parameter 1 for setting the gain
K2	PI	Parameter 2 for setting the gain
LEV-K2	PI	Level to start with the second gain (K2)
TN/TZ	PI	Integration time
INTHLD	II	Hold the integration
INTRES	II	Reset the integration
RESET	II	Reset the controller
LIMVAL	II	Value for the limitation
WEIGHT	PI	Value for the weighting
OUT	OI	Output

## Function

This controller is equipped with a PI controller and a second gain function depending on the difference between reference and feedback value.

The gain is preset by using parameter P1 (K1) and the reset time by using parameter P4 (TN/TZ).

If the feedback/reference deviation lies above the preset difference P3 (LEV\_K2), a second gain function P2 (K2) becomes effective. This ensures that the control system's response is less forceful, if the deviation value is within the range of its desired value, and more forceful, if this range is exceeded.

The value of the integration is hold with the input INTHLD and is set to zero with INTRES. The output of the controller is set to zero, if the signal RESET is active.

The input LIMVAL provide the minimum and maximum limit values.

The controller output is weighted (0...100%) by using parameter P5 (WEIGHT).

## Special start logic

## SSL

### Summary

This block **Special Start Logic** is used to create the control signals and the limit for die SC (Special Controller) depending of the actually value.

### Call **SSL\_471**

### Connections *Table 1*

Name	Type	Description
STOSH	II	Reset of the self-holding logic
IN_P	II	Positive input of the comparator (actual value)
IN_N	II	Negative input of the comparator (parameter)
RESIG	II	Reset the start logic
STRT	II	Logic active
REL	II	Release
INTVAL	PI	Internal value for the limit
EXVAL	II	External value for the limit
ON	OI	Start logic on
OFF	OI	Start logic off
SPCREL	OI	Release for the controller
VALOUT	OI	Value for limit

### Function

The description starts with the start situation, that all logical inputs are zero. The input IN\_P is connected to the actually value, the input IN\_N to an external value (parameter or constant). The parameter P1 is set to the start limit and the input EXVAL is set to the max. limit. in this case the start logic is ON (output).

The inputs REL and STRT (set to -1) set the output SPCREL (release signal for the controller). The start logic changed to off, when the input IN\_P increased higher than the input IN\_N **or** when the signal RESIG is set. The self-holding is active and can to be reset with the input STOSH.

The start logic is ON again, when the signal STRT is set to zero.

**Block numbers and pin addresses** *Table 2*

# Tension reference

# TERE

## Summary

The block **T**ension **R**eference is used for the tension control with and without an actual tension value. This block consists on internal tension reference, tension reduction and tension ramp.

**Call**    **TERE\_474**

**Connections**      *Table 1*

<b>Name</b>	<b>Type</b>	<b>Description</b>
TREF	II	External tension reference
FOLEXT	II	Signal setting the external reduction value
TRED_IN	PI	Internal reduction value
TRED_EX	II	External reduction value
CALCDIA	-	Actual diameter
DIARED	PI	Value of diameter starting the reduction
MINREF	PI	Value of the minimum tension
FOLINR	II	Signal setting the internal tension reference
INREF	PI	Internal tension reference
T	PI	Ramp time
SET	II	Signal setting the ramp on SETVAL
SETVAL	II	External setting value
OUT	OI	Output

### Function

The input reference value (TREF) is to connected to a tension reference. The tension of 100% is the internal value of 20000.

The parameter P1 (TRED\_IN) or the input TRED\_EX, chosen with FOLEXT, is used to reduce the tension depends of increasing diameter. The reduction begins with the diameter higher than P2 (DIARED)

At the maximum diameter (4000 dec.) the tension reference is :

$$\text{OUT} = \text{TREF} * \left( 1 - \frac{\text{TRED\_IN or TRED\_EX}}{20000} \right)$$

Tension reference is limited at the lower value by the parameter P3 (MINREF).

Setting the signal FOLINR the tension value is from the parameter P4 (INREF).

The selected value is passed through the integrator. Time is to set with the parameter P5 (T).

The signal SET is used to set the output to the value of the input SETVAL.

**Block numbers and pin addresses** Table 2

FB number	474		Scaling factor	Range of values		Default	Unit
				max.	min.

# Torque from tension

# TOTE

## Summary

The block **TO**rque **TE**nson is used to transfer the tension to torque and to weight the output.

## Call TOTE\_475

## Connections *Table 1*

Name	Type	Description
ACT	II	Signal to activate the output
IN1	II	Input for the adjusted tension reference
IN2	II	Input for the tension controller
IN3	II	Multiplier for calculation
WEIGHT	PI	Value weighting the output
OUT	OI	Output

## Function

This block is to activate the tension torque. The inputs IN1 and IN2 (max. 20000) are calculated with the input IN3, which is connected to the actual diameter CALCDIA. This means with the maximum input, that the output reached the maximum at the maximum diameter. The level of 20000 (reference) is also set to the level of 4000 (current).

The needed torque getting the tension is to be set with the parameter P1.

**Block numbers and pin addresses** Table 3

FB number	475		Scaling factor	Range of values		Default	Unit
				max.	min.

## Velocity reference

## VERE

### Summary

The block **VE**locity **RE**ference is used to adjust the value and set the polarity.

### Call **VERE\_469**

### Connections *Table 1*

Name	Type	Description
IN	II	Reference input
MUL1	PI	Multiplier from parameter
CGHMUL	II	Signal to change multiplier from the internal value (5000)
REFPOL	II	Set polarity
ADDVAL1	PI	Value to add to the reference
ADDPOL1	II	Signal to set the polarity of the added value
RATREF	OI	Adjusted reference (rated)
POLREF	OI	Adjusted reference with the set polarity
OUT	OI	Output of this block

### Function

The input IN get the main external velocity reference. For some applications it is necessary to adjust the reference to lower than 100%. This is possible with the parameter P1 (MUL1). The polarity is set with the signal REFPOL and includes the signal re- or unwinder and the winding direction.

The parameter ADDVAL1 is used to the overmodulation or to the commissioning.

**Block numbers and pin addresses** Table 2

FB number	469		Scaling factor	Range of values		Default	Unit
				max.	min.

## Winder logic

# WILO

### Summary

In the depending of the diameter (CALCDIA) the output will set for a time of T\_ON.

### Call WILO\_476

### Connections *Table 1*

Name	Type	Description
SIGREW	II	Signal for the rewinding or unwinding
CALCDIA		Calculated diameter (internal connection)
IN	II	Input of the level
T-ON	PI	Time setting the output
OUT	OI	Output

### Function

The output is set to -1, when the difference from CALCDIA and the input IN change the polarity from 0 to -1. The output stays at -1 during the time T-ON. The input IN can be connected to a parameter or to an analogue input.

The direction of the polarity is depended of the signal SIGREW.

When the signal SIGREW is zero (agree with an unwinder), the output goes to logic one decreasing the diameter CALCDIA lower than IN.

When the signal SIGREW is -1 (agree with a rewinder), the output goes to logic one increasing the diameter CALCDIA higher than IN.

Please remind, that the maximum value of the calculated diameter (CALCDIA) is 4000.

# Disable Fault

# DISF

## Summary

The block **DISF** (**DIS**able **F**ault) is used to disable one or more faults when activ fault signals occur.

## Call DISF\_487

## Connections *Table 1*

Name	Type	Description
IN	II	Signal to disable the faults
Mask 1	II*	Input mask to disable the faults in Fault Word 1 (111.01)
Mask 2	II	Input mask to disable the faults in Fault Word 2 (111.02)
Mask 3	II	Input mask to disable the faults in Fault Word 3 (111.03)

## Function

If the control input "DisFault" is set (to  $\neq 0$ ) and one or more bits in the inputs "Disable.[MASK1]" to "Disable.[MASK3]" are set, the same bits in the signals "Fault Word 1" to "Fault Word 3" (111.01 - 111.03) will not be set and the corresponding faults will not be activated when the reason for these faults occurs.

If the control input "DisFault" is reset (to 0) and the reasons for the faults are still activ, the corresponding fault will set immediately

Table : Reaction of DCS500 when the occasion of the disabled fault occurs

Bit	Fault Word 1 (Rem.)	Fault Word 2 (Rem.)	Fault Word 3 (Rem.)
15	Field Ex.1 commu. error F33 (3)	Motor overspeed F37 (1)	Rev fault F65 (1)
14	Field Ex.1 overcurrent F32 (3)	Motor stalled F23 (1)	Master-Slave fault F66 (1)
13	Not in synchronism F31 (3)	Field Ex. 2 not OK F43 (3)	Timeout fieldbus F60 (1)
12	Mains overvoltage F30 (3)	Field Ex. 1 not OK F42 (3)	Null
11	Mains undervoltage F29 (2)	Local & Disconnected F20 (3)	Null

## Switch parameter and transfer

# SWPT

### Summary

The block **SWPT** (**SW**itch **P**arameter and **T**ransfer) is used to switch parameters with changover and to transfer to another parameter.

### Call **SWPT\_488**

### Connections *Table 1*

Name	Type	Description
EN	II	Enable data transfer
ACT	II	Activate the switching
IN1.1	PI	Value of parameter 1 for the switch 1
IN1.2	PI	Value of parameter 2 for the switch 1
OUT1	PI	Destination address for the transfer of switch 1
IN2.1	PI	Value of parameter 1 for the switch 2
IN2.2	PI	Value of parameter 2 for the switch 2
OUT2	PI	Destination address for the transfer of switch 2
IN3.1	PI	Value of parameter 1 for the switch 3
IN3.2	PI	Value of parameter 2 for the switch 3
OUT3	PI	Destination address for the transfer of switch 3
DONE	OI	Set to -1 when the data transfer is completed

## Function

When the input EN is <>0 the selected parameters will be written to the parameters indicated by the destination addresses. With EN = 0 the data transfer not occurs.

With the input ACT = 0 the parameters at INx.1 (with x in 1,2,3) are selected for the transfer. With active input ACT (<>0) the parameters at INx.2 are selected.

When the data transfer of this block starts, the output signal DONE is 0. This signal get -1 when the transfer of the whole block is completed.

Attention ! Let no destination address (P3,P6,P9) with 0. It can give rise to unintended reactions.  
(alternative e.g. set the address of a not used parameter)

### Guide for using Function Block in the Graphical Application Designer

Definable attributes : *Task number / Execution order, Comment text (several languages), General text (one language)*

## ***Index of Function Block description***

<b>ABS</b> .....	6-1	<b>MULDIV</b> .....	6-40
<b>ACW</b> .....	6-65	<b>MUX-I</b> .....	6-41
<b>ADD</b> .....	6-2	<b>OR</b> .....	6-43
<b>AND</b> .....	6-4	<b>OSC-B</b> .....	6-45
<b>BITGET</b> .....	6-6	<b>PAR</b> .....	6-47
<b>BITSET</b> .....	6-7	<b>PARW</b> .....	6-75; 6-93
<b>COMP-I</b> .....	6-9	<b>PI-I</b> .....	6-48
<b>CONV-BI</b> .....	6-11	<b>SC</b> .....	6-76
<b>CONV-IB</b> .....	6-15	<b>SETF</b> .....	6-94
<b>COUNT</b> .....	6-19	<b>SR</b> .....	6-51
<b>DIAC</b> .....	6-68	<b>SR-D</b> .....	6-52
<b>DIAREL</b> .....	6-71	<b>SSL</b> .....	6-78
<b>DISF</b> .....	6-91	<b>SUB</b> .....	6-54
<b>DIV</b> .....	6-21	<b>SW-C1</b> .....	6-55
<b>DT</b> .....	6-72	<b>SWPT</b> .....	6-97
<b>FILT</b> .....	6-22	<b>TERE</b> .....	6-80
<b>FUNG-1V</b> .....	6-23	<b>TOFF</b> .....	6-57
<b>INT</b> .....	6-26	<b>TON</b> .....	6-59
<b>INV</b> .....	6-29	<b>TOTE</b> .....	6-83
<b>LIM-N</b> .....	6-31	<b>TRII</b> .....	6-85
<b>LSW</b> .....	6-73	<b>VERE</b> .....	6-86
<b>MAX</b> .....	6-34	<b>WILO</b> .....	6-88
<b>MIN</b> .....	6-35	<b>WRITE</b> .....	6-61
<b>MONO</b> .....	6-36	<b>XOR</b> .....	6-63
<b>MUL</b> .....	6-39		

## **Appendix A - Relationship between Application blocks and Firmware releases**

<b>related GAD Libraries</b>	1.01	1.21	1.22	1.30
<b>related Firmware release</b>	≤ 21.108	21.121	21.122	21.123
<b>Application Blocks</b>
