4. To create a configuration for logging tags in a time series segment, select the entry "Logging tag configuration".
   To create a configuration for logging tags in a single value segment, select the entry "Single value configuration logging tag".
5. Enter the name of the configuration under "Configuration name".
6. Under "Calculation mode", select the data to be written if no current value is available.
7. (Optional) If the configuration is for logging tags with the numeric data type, you can output texts or graphics from a text list or graphic list in the standard column instead of the tag value. See Assigning text lists and graphic lists (Page 7440).
8. Set the other settings as described below.
9. Confirm your entries with "OK".

Note

To not use the default column title for the standard column, set a display name in the local configuration of the data source item. See Setting a display name for standard column (Page 7443).

Editing a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click a configuration for logging tags.
4. Edit the configuration settings.
5. Confirm your entries with "OK".

The changes are applied the next time you read in the Runtime data.

Additional settings for time series segments

In time series segments, the following additional settings are available for logging tags:

Setting	Description
"Interval"	Only for the "Stepped" and "Interpolated" calculation modes.
"Columns" > "Quality Code"	(Optional) Change the default settings of the optional "Quality Code" column. See Configuring optional columns (Page 7439).

Additional settings for single value segments

In single value segments, the following additional settings are available for logging tags:

Setting	Description
"Time stamp"	Determine the date and time for which the value is read. Proceed as described below.
"Show captions"	Define whether a header is displayed in the columns for the time stamp, the data source item and the quality code.
"Show time stamp"	Determine whether and where this information is displayed in the table. The information is always in relation to the value cell.
"Show data source item"	
"Show quality code"	

To set the "Time stamp", select one of the following options:

	Absolute time information	Select a date and a time. The information is absolute.
	Relative time information	Select a reference time and a time interval. The information is relative to the current date.
	Read time information from cell	Applies the value of the cell currently highlighted in the Excel file. Make sure that the cell supplies a valid time.
	Read time information from tag	Applies the value of the set tag. Make sure that the tag supplies a valid time. Possible data types: • DateTime • String • Integer

See also

Calculation modes for data source elements (Page 7447)

Creating or editing configurations for tags:

Requirement

- The "WinCC Unified" tab is visible in Excel.

Creating a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration": 
3. Click "New Configuration> Tag single value configuration".
4. Enter the name of the configuration under "Name".
5. (Optional) If the configuration is for tags with the numeric data type, you can output texts or graphics from a text list or graphic list in the standard column instead of the tag value. See Assigning text lists and graphic lists (Page 7440).
6. Set the other settings as described below.
7. Confirm your entries with "OK".

Note

To not use the default column title for the standard column, set a display name in the local configuration of the data source item. See Setting a display name for standard column (Page 7443).

Editing a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration".
3. Click a configuration for tags.
4. Edit the configuration settings.
5. Confirm your entries with "OK".

The changes are applied the next time you read in the Runtime data.

Settings for single value segments

In single value segments, the following settings are available for tags:

Setting	Description
"Show captions"	Select whether a header is displayed in the columns for the time stamp, the data source item and the quality code.
"Show time stamp"	Select whether the time stamp is output with the value.
"Show data source item"	Select whether the quality code is output with the value.
"Show quality code"	Select whether the quality code is output with the value.

Creating or editing configurations for contexts

Requirement

- The "WinCC Unified" tab is visible in Excel.

Core statement

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

3. Click "New Configuration".
4. Select the entry "Configuration context".
5. Enter the name of the configuration under "Configuration name".
6. (Optional) Change the default settings of the optional columns. The optional columns are used to display important contextual information.
See Configuring optional columns (Page 7439).
7. Confirm your entries with "OK".

Note

To not use the default column title for the standard column, set a display name in the local configuration of the data source item. See Setting a display name for standard column (Page 7443).

Editing a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

3. Click a configuration for contexts.
4. Edit the configuration settings.
5. Confirm your entries with "OK".

The changes are applied the next time you read in the Runtime data.

Creating and editing configurations for user-defined columns

Requirement

- The "WinCC Unified" tab is visible in Excel.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click "New Configuration > User-defined column configuration".
4. Enter the name of the configuration under "Configuration name".
5. Under "Formula", select one of the following options:
   - Enter a fixed string.
     The string is transferred into each cell of the column.
   - Enter an Excel formula.
     The formula is copied into each cell of the user-defined column and adapted to the respective row.
     To prevent a part of the formula from being adjusted, place the character "$" in front of it.
     Example

Formula in configuration		=B2+C2	=B$2+C2
Adapting the formula in the report	in line 2	=B2+C2	=B2+C2
	in line 3	=B3+C3	=B2+C3
	in line 4	=B4+C4	=B2+C4

   Note

   No validity check

   The formula is not tested for correctness during either input or dynamic adaptation.

6. Confirm your entries with "OK".

Adding or editing configurations for audit

Introduction

Check mode

The check mode of the configuration of an audit data source item determines

- Whether an integrity check is performed when the Runtime data is read, and what is checked. You can output the overall result of the check in the table header row in the "Audit status" field.
- Which audit data records are provided in the data table.

Possible check modes:

"None"	Provides the data for all audit data records that fall within the requested time range. No integrity check is performed. Default setting
"Check only"	Checks all audit data records that fall within the requested time range without providing their data. It is tested whether data records have been manipulated, deleted or added.
"Check entries"	Check the audit data records and provides their data that fall within the queried time range and that have not been deleted from the Audit Trail or subsequently added. It is checked whether data records have been manipulated.
"Check all"	Checks all audit data records and provides their data that fall within the queried time range. It is tested whether data records were manipulated, deleted from the audit trail or subsequently added.

Filter type

An Audit data record consists of two entries:

- An entry for the user expectation
- An entry for the system response.

User expectation and system response may differ. In addition, there are situations in which only one of the two data records is created.

The filter type controls which data records and which entries are included in the report.

Possible filter types:

Filter type	User expectation equals system response	User expectation does not equal system response	Data record entry for user expectation or system response is missing
"Show all data in detail"	Both data record entries are inserted.		The existing data record entry is inserted.
"Show data and conformity errors"	The data record entry with the user expectation is inserted.	Both data record entries are inserted.	
"Show only data with conformity errors"	No data record entry inserted.		

Requirement

- The "WinCC Unified" tab is visible in Excel.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click "New Configuration > Audit configuration".
4. Enter the name of the configuration under "Name".

5. Select a check mode:
6. Specify a filter type.
   Preset value: "Show data and conformity errors"
7. (Optional) Change the default settings of the optional columns. The optional columns are used to display the audit attributes.
   See Configuring optional columns (Page 7439).
8. (Optional) To further filter the inserted content, define a filter query.
   The filter query can consist of up to two conditions. Proceed as follows:
   - Under "Filter", click "+" or "Add new condition row".
   - Select an Audit attribute, an operator and enter the value of the attribute.
   - Optional: Use "+" or "Add new condition row" to create additional conditions. Select whether the conditions are to be linked with a logical AND or OR.
9. Confirm your entries with "OK".

Note

To not use the default column title for the standard column, set a display name in the local configuration of the data source item. See Setting a display name for standard column (Page 7443).

Editing a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   
3. Click a configuration for Audit.
4. Edit the configuration settings. You have the same options as when creating the configuration.
5. Confirm your entries with "OK".

The changes are applied the next time you read in the Runtime data.

Examples of the configuration of the filter type

The following table contains examples of data records that were generated in Runtime through changes to tags monitored by Audit:

Data record ID	Tag name	Modified by	Old value	New value	Description
1A	Motor1_Speed	User1	0	10	An operator changes the speed of a motor in an I/O field of an HMI screen.
1B	Motor1_Speed	System	0	10	User expectation and system response are identical.

Data record ID	Tag name	Modified by	Old value	New value	Description
2A	ValvePercen-tile	User1	0	100	An operator opens a valve using a slider on an HMI screen. The valve has a physical blockage and cannot be opened. Therefore, no data record entry for the system response is generated.
3A	ValvePercen-tile	User1	0	99	A physical block has been removed and the operator repeats the entry. The valve reacts, but cannot be fully opened. User expectation and system response differ.
3B	ValvePercen-tile	System	0	49	
4B	Mo-tor2_Speed	System	0	20	An operator changed the speed of another motor. The resulting data record was manipulated, and the user expectation entry was deleted. There is only one entry for the system response.

The following table shows which data record entries are inserted into the data table depending on the filter type selected when generating the report:

Data record ID	Tag name	Modified by	Old value	New value
Filter type "Show all data in detail"				
1A	Motor1_Speed	User1	0	10
1B	Motor1_Speed	System	0	10
2A	ValvePercentile	User1	0	100
3A	ValvePercentile	User1	0	99
3B	ValvePercentile	System	0	49
4B	Motor2_Speed	System	0	20
Filter type "Show data and conformity errors"				
1A	Motor1_Speed	User1	0	10
2A	ValvePercentile	User1	0	100
3A	ValvePercentile	User1	0	99
3B	ValvePercentile	System	0	49
4B	Motor2_Speed	System	0	20
Filter type "Show only data with conformity errors"				
2A	ValvePercentile	User1	0	100
3A	ValvePercentile	User1	0	99
3B	ValvePercentile	System	0	49
4B	Motor2_Speed	System	0	20

Select configuration

Requirement

- The "WinCC Unified" tab is visible in Excel.
- A segment with a data source item is available.
- There is a user-defined configuration for the type of the data source item.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Select the segment.
   The segment is extended by the area for the data source items.
3. Select the desired configuration from a data source item in the drop-down list.
4. Click "OK".

Result

The changes are applied the next time you read in the runtime data.

Overwrite a configuration locally

A local configuration overwrites the configuration selected at the data source item. It applies only to the data source item for which it was entered.

Requirement

- The "WinCC Unified" tab is visible in Excel.
- A segment with a data source item is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Select the segment.
   The segment is expanded to include the plant complex for the data source items.
3. Move the mouse over a data source item and click "Edit".
   You create a local configuration that first adopts the values of the original configuration.
4. Enter a name for the local configuration.
5. (Optional) Set a display name. See Setting a display name for standard column (Page 7443).
6. Make the remaining settings as required.
   You can make the same settings as in the default and custom configurations.
7. Confirm your entries with "OK".

Result

The changes are applied the next time you read in the Runtime data.

Delete configuration

Requirement

A configuration is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration".
3. Move the mouse to a configuration.

   Note
   Default configurations cannot be deleted
   You can edit default configurations but not delete them.

4. Click "Delete".

Result

- The configuration is deleted.
- Data source items with this configuration obtain a local configuration with the same settings.

Configuring optional columns

Introduction

In time series segments, data source items of the following types have optional columns:

- Logging tag
- Logging alarm
- Alarm statistics
- Audit
- Context

The optional columns of a data source item depend on its type. The configuration of the data source items controls whether and how the data table shows these columns.

This section describes how to configure the optional columns.

Requirements

The data source item configuration is open. The configuration must apply to a time series segment.

Showing and hiding columns

1. To show an optional column in the data table, enable the option for the desired column in the "Columns" area.
2. To hide a column, disable its option.

Changing the column title

The data table uses as default column titles the identifiers you see in the "Columns" area. To change the default column titles, do the following.

1. In the "Columns" area, move the mouse pointer to an optional column.
2. Click the button with the pin.
3. Assign a unique column title.

Note

Localization

The column title is stored in the Runtime language currently set in the basic settings of the add-in.

To localize the column title, change the Runtime language and repeat your entry in the new language.

Changing the column sequence

To change the order of the optional columns in the data table, proceed as described in Changing the column sequence (Page 7444).

Assigning text list or graphic list

The values of numeric columns can be replaced by texts or graphics when the Runtime data is read in.

To assign a suitable text list or graphic list to the property, proceed as described in Assigning text lists and graphic lists (Page 7440).

Assigning text lists and graphic lists

Introduction

If standard columns and optional columns of data source items output numerical values, you can assign text lists and graphic lists to these columns. When the Runtime data is read in, the cell values of these columns are replaced by texts or graphics from the assigned lists.

This function improves the readability of the report and helps to draw the reader's attention to important information.

Note

Restrictions

- Tags/logging tags
  Assign a text list or graphic list to the standard column of data source items with a Tag or Logging tag type only if the tag or logging tag has a numeric data type.
  You can assign a text list or graphic list to the optional "Quality Code" column regardless of the data type of the tag.
- User-defined columns
  It is not possible to assign a text list or graphic list for data source items with the User-defined column type.
- Context and audit
  Usually, the names of context objects and audit objects displayed in the standard column do not contain purely numerical values. It is not recommended to assign a text list or graphic list.

Example

Add two data source items with the same logging tag to a time series segment.

For the first data source item, use the default configuration. This causes the report to output the tag value in the standard column.

For the second data source item, select a configuration in which a graphic list is assigned to the standard column. The graphic list contains representational graphics staggered by value range. As a result, the report outputs a graphic in the standard column.

After reading in the Runtime data, the standard column of the second data source item makes readers of the report aware of limit violations. Readers can get the exact tag value from the standard column of the first data source item.

Requirements

- A segment with a data source item was created in the add-in.
- Suitable text lists or graphic lists have been configured in engineering for the connected data source.

Assigning text lists and graphic lists to the standard column

1. Click on "Segments" in the "Configuration" group.
2. Select the segment.
   The data source items of the segment are displayed.
3. Move the mouse over a data source item and click "Edit".
   The local configuration of the data source item opens.

4. Select a suitable list under "Assign text/graphic list".
5. To preview the selected list and its graphics or texts, click the "i" button.
   To hide the preview, click the "i" button again.

Assigning optional columns to text lists and graphic lists

1. Click on "Segments" in the "Configuration" group.
2. Select one of the following options:
   To make the assignment apply to a specific data source item, follow these steps:
   - Select the segment.
     The data source items of the segment are displayed.
   - Move the mouse over the data source item and click "Edit".
     The local configuration of the data source item opens.

   To make the assignment apply to multiple data source items of the same type, follow these steps:
   - Click "Data source item configuration": 
     You can see all default and custom configurations.
   - Click on the desired configuration.
     The configuration opens.
3. In the "Columns" area, click the following button next to the desired optional column:

   

   An interface for assigning a text list or graphic list is loaded into the add-in.
4. Select the desired graphic list or text list from the drop-down list.
5. To preview the selected list and its graphics or texts, click the "i" button.
   To hide the preview, click the "i" button again.

   Note

   If you are connected offline to the data source, no preview of graphic lists is available.

6. Confirm your entries.

Result

When the Runtime data is read in, the assigned lists are searched for an entry that matches the actual cell value:

- If a matching entry is found, the corresponding text or graphic is inserted into the data table.
- If no matching entry is found, the actual cell value is inserted.

Note

The assignment of graphic lists slows down the import of the Runtime data into the Excel add-in.

Standard column (Page 7406)

Basic information on segments (Page 7404)

Setting a display name for standard column

Introduction

You can assign a display name for the standard column of a data source item. When a display name is set, it is used in the data table instead of the default column title and is listed in the table header row.

Display names make reports clearer, for example, when data source items for contexts or tags have very long names.

You set the display name in the local configuration of the data source item.

Requirement

- The "WinCC Unified" tab is visible in Excel.
- There is a segment with a matching data source item.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Expand a segment by clicking on it.
   The area for adding and editing data source elements appears.
3. Move the mouse pointer to the data source item and click "Edit".
   The local configuration of the data source item opens.
4. Enter the desired column title in "Display name".
   The column title must be unique within the segment.

   Note

   Localization

   The column title is stored in the Runtime language currently set in the basic settings of the add-in.

   To localize the column title, change the Runtime language and repeat your entry in the new language.

5. Confirm your entry with "OK".

Result

- The data table uses the display name as the column title for the standard column of the data source item.
- As long as the following conditions are met, the "Display name" column is inserted into the table header row:
  - Display of the header row in table header row is enabled.
    Make this setting at the segment.
  - A display name is set for at least one data source item of the segment.

  The column lists the display names of all data source items. If no display name is set for a data source item, its cell remains empty.

Note

- If you assign a different configuration to the data source item, the display name is retained.
- To return to the display of the default column title after assigning a display name, enter the name of the data source item under "Display name".

Standard column (Page 7406)

Overwrite a configuration locally (Page 7438)

Changing the column sequence

Introduction

For a time series segment, you can change the default column order of the data table.

You have the following options:

- Specify the order which the data source items have in the data table.
- For each data source item: Set the order of its optional columns.

Note

The time stamp column always appears first.

Requirement

- The "WinCC Unified" tab is visible in Excel.
- A time series segment has been created.

Change the order of data source items

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click the time series segment in the list of time series segments.
   The data source items of the segment are displayed.
3. Left-click a data source item and move it up or down using drag-and-drop operation.

Result

The order of data source items in the segment interface is changed.

The next time the Runtime data is read in, the data table outputs the data source items in this order.

Changing the order of optional columns

Procedure

1. Select one of the following options:
   To change the column order of a particular data source item, follow these steps:
   - Select the segment.
     The data source items of the segment are displayed.
   - Move the mouse over the data source item and click "Edit".
     The local configuration of the data source item opens.

   To change the column order for all data source items that use the same configuration, follow these steps:
   - Click "Data source item configuration":

     

     You can see all default and custom configurations.
   - Click on the desired configuration.
     The configuration opens.
2. Move the mouse pointer to a column under "Columns".
   The columns you see depend on the type of data source item.
3. Move the column up or down using the arrow buttons or drag-and-drop.

Result

The order of the optional columns in the configuration is changed.

The next time the Runtime data is read in, the data table outputs the optional columns in the changed order.

Basic information on segments (Page 7404)

Configuring optional columns (Page 7439)

Reading Runtime data in Excel

Note

Reading in Runtime data in Excel is used for testing. It is not intended for mass retrieval of data, as is the case when report jobs are executed in Runtime.

Requirement

An online connection is established.

Reading in all segments

1. Select "WinCC Unified > Segments".
2. Click "Update all":

Reading in individual segments

1. Select "WinCC Unified > Segments".
2. Next to a segment in the list of segments click, "Update":

Result

The segment or segments are run. The Runtime data of your data source items are read into Excel.

Note

Controlling the column width and row height

When the automatic adjustment of the column width and row height is disabled in the segment properties, the text read in may be truncated or the formula results are replaced with "#" characters.

Check the column widths and row heights and adjust them manually, if required, or select automatic adjustment. Manual adaptations only apply in the Excel add-in. They are not included in the generated reports.

Note

Removing Runtime data from report template

Remove the Runtime data from the report template before you save the report template and make it available for uploading to Runtime.

To do this, click the "Delete Runtime data" button  in the toolbar of the Excel add-in.

Diagnostics during the data query

Successful execution of the data query is documented by the add-in with a status message in the table.

If an error occurs during the data query, a general error message is displayed under status. In addition, detailed error messages are displayed in the "ErrorLog" worksheet.

Calculation modes for data source elements

If there is no current value for a data source item for a requested point in time, the following calculation modes are available.

Calculation modes for tags

The following calculation modes are available for tags of a time series segment:

Calculation mode	Description
Raw	The actual value available for the specified period. If no data are available, no value is output.
Stepped	If no data are available, the last value is used. With this mode you can also use values with an invalid quality code.
Interpolate	The values are interpolated linearly for the specified time period. With this mode you can only use values with a valid quality code.

The following calculation modes are available for tags of a single value segment:

Calculation mode	Description
Interpolate	The values are interpolated linearly for the specified time period. With this mode you can only use values with a valid quality code.
Left	If no data is available, the last value before the specified period is used.
Right	If no data is available, the last value after the specified period is used.

Create or edit configurations for logging tags (Page 7429)

Making general settings

Adapting the work area

Undocking and moving the add-in

To enlarge your working area, you can undock the Excel add-in:

1. Open the drop-down list in the header of the add-in.
2. Click "Move".
3. Move the mouse pointer to the desired location and click the left mouse button.
4. To move the add-in again, keep the left mouse button pressed in the header of the add-in and move the mouse.
5. To dock the add-in again, double-click in the header of the add-in.

Adapting the size of the add-in

1. Open the drop-down list in the header of the add-in.
2. Click "Resize".
3. Move the mouse pointer to the left to make the add-in wider or to the right to make it narrower.
4. Left-click when you have reached the desired size.

Changing the language

Changing the add-in language

The Excel add-in automatically uses the same user interface language as Excel. If you are using a language for Excel that is not included in the Unified options, English is used as the default language.

You can select the language for the contents of the report independently of the interface. To select another language, the language must be configured in Runtime.

Selecting the language for the report

1. Select "WinCC Unified > Segments".
2. Click "Basic settings":

3. Under "Runtime language", select the language of the report content.
4. Under "Query language" you select which language data queries have that require user input, e.g. filter definitions.

Zooming in the add-in

Procedure

To zoom in or out of the display in the add-in, press <CTRL> and move the mouse wheel.

Undo and redo

The Excel functions "Undo" and "Redo" are not available in the add-in.

Tips on design and layout

This section includes tips on the visual design of reports. The apply for:

- Report templates
- Reports that were generated as XLSX file

Note

Deviating PDF results

A PDF report created by LibreOffice can deviate in content or layout from a PDF report generated with Excel, for example, if the report template uses common Excel features that LibreOffice does not support, such as special fonts or chart types.

Arranging segments

Always place the segments of a report template side by side or each in their own worksheet.

Because the data tables of the segments grow dynamically, tables can overlap when segments are placed one below the other. In the add-in, this causes an error of the OfficeExtension.Error class when reading in the Runtime data.

Changing the column sequence

See section Changing the column sequence (Page 7444).

Adapt column width and row height

For each segment of a report template, check whether the column widths and row heights of your data table are wide or high enough for the values to be read. If this is not the case, texts in the generated report are truncated or the formula results are replaced with "#" characters.

To do this, select one of the following options:

- In the properties of the segments, select the options for automatic adjustment of the column width and row height.
- Click "Update all" in the report template.
  Values are imported to Excel from the data source. Check the column widths and row heights and adjust them manually, if required.

Note

The manual adaptations apply only in the Excel add-in. They are not included in the generated reports.

Replacing numerical values

If columns of a data source item output numeric values, you can assign text lists and graphic lists to the columns. When the Runtime data is read in, the cell values of these columns are replaced by texts or graphics from the assigned lists. This improves the readability of the report and helps to draw the reader's attention to important information.

Example: Visualizing limit violations of tags with graphics

See section Assigning text lists and graphic lists (Page 7440).

Preparing imported Runtime data

Adjust the cell formatting of the Runtime data, for example, font, color, alignment, or number format. The rows inserted when reading the Runtime data adopt the formatting.

Add diagrams, pivot tables or formulas that graphically visualize, structure or evaluate the data imported from Runtime.

Note

If you have read Runtime data into the report template for better data preparation, remove it before saving the report template and making it available for upload to Runtime.

To do this, click the "Delete Runtime data" button in the toolbar of the Excel add-in.

Set up page

Use "File > Print > Set up page" to define details for printing the report, for example:

- Alignment of the report (portrait format or landscape format)
- Scaling, for example, to print all columns on one page
- Inserting a user-defined header or footer

The print settings set in the report template are applied in Runtime when a report job is executed for PDF generation.

Renaming worksheets and segments

When you add a segment to a report template in the add-in, a table is created in Excel. The add-in addresses the table by the name of the worksheet and segment.

Do not rename worksheets after adding segments.

Do not change the table name of a segment using the Excel property "Table name". Edit the segment in the add-in and rename it there.

17.3.4.12 Rearranging columns at runtime

Introduction

You can rearrange the table columns in the following table-based controls:

- Alarm control
- Trend companion
- Process control
- Parameter set control
- System diagnostics control

Requirement

Configuration of the control in the engineering requires rearrangement of the columns.

Procedure

To move a column, drag-and-drop its column header onto the column header of another column.

Note

The time column cannot be moved.

Result

The moved column is inserted at the position that the cursor had when the drag-and-drop movement ended.

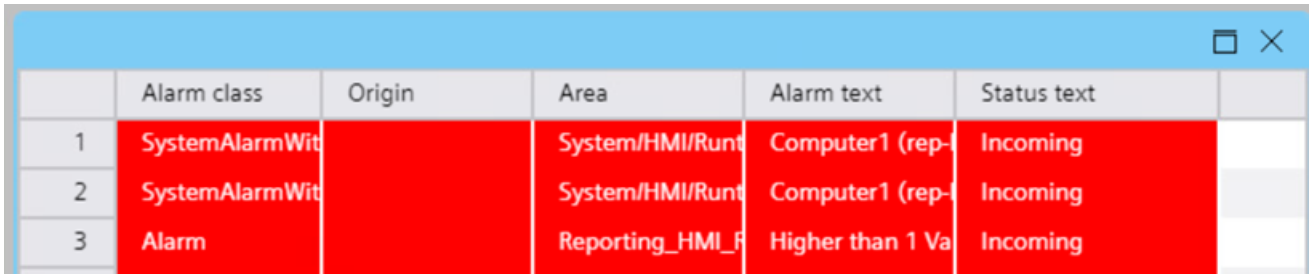
The new arrangement only applies to the current client. If you change the page or refresh the browser window, the arrangement is lost.

Note

If you move a column next to the hidden column and then unhide it, it is always shown to the right of the moved column when it is unhidden.

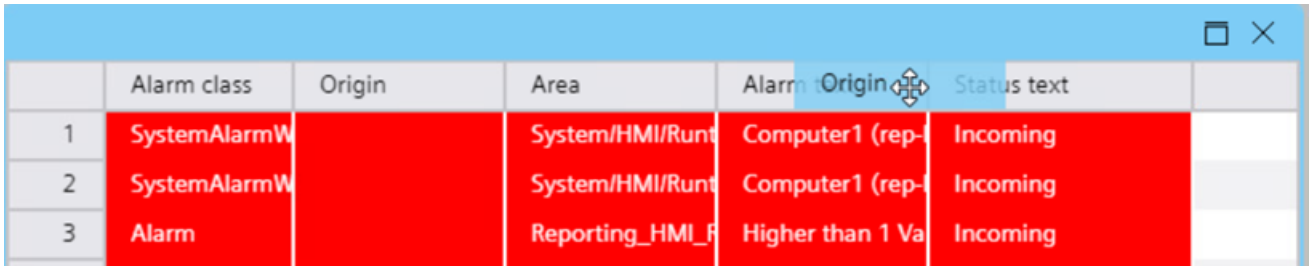
Example 1: Inserting columns to the left or the right

The procedure is illustrated based on the example of an alarm control. In the initial situation, the table of the alarm control has the following column arrangement:

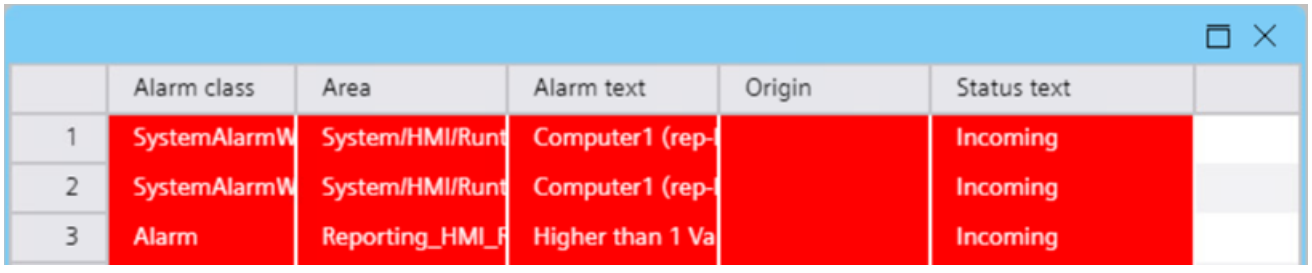


To insert the "Origin" column to the right of the "Alarm text" column, proceed as follows:

1. Use drag-and-drop to move the column header of "Origin" to the right half of the column header of the "Alarm text" column.

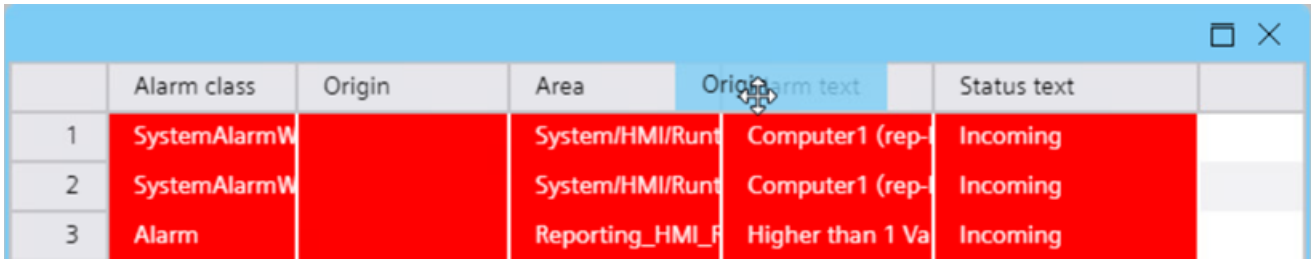


2. The "Origin" column is inserted to the right of the "Alarm text" column.



To insert the "Origin" column to the left of the "Alarm text" column, proceed as follows:

1. Use drag-and-drop to move the column header of "Origin" to the left half of the column header of the "Alarm text" column.



2. The "Origin" column is inserted to the left of the "Alarm text" column.

Example 2: Reordering of columns in combination with hidden columns

The example illustrates the rearrangement of columns in combination with hidden columns.

- The alarm view has the same column order as in Example 1.
- The alarm view has been configured in the engineering system in such a way that the display of the "Origin" column is controlled dynamically in runtime by setting a tag.

To reorder the columns in combination with hidden columns, proceed as follows:

1. Hide the "Origin" column by setting the tag.
2. Insert the "Status text" column to the left of the "Area" column.
3. Unhide the "Origin" column by setting the tag.

The columns have the order "Alarm class", "Status text", "Origin", "Area", "Alarm text".

17.3.4.13 Process diagnostics

Basics of supervision with ProDiag

Introduction

The TIA Portal functionality, ProDiag (Process Diagnostics), is used to monitor and determine errors that occur in your plant or machine. You can use ProDiag to show the type of error, the cause of the error and the location of the error on the HMI device.

Use

You can use ProDiag functions to monitor your plant and to visualize it on an HMI device. The main objective of ProDiag is the reduction of downtime and loss of production after an error occurs, and the avoidance of errors using timely warnings. Diagnostic and display objects provide specific information for the operator for troubleshooting and show the processes on an HMI device on site.

Principle

In STEP 7, you create operand supervisions and configure the settings according to your requirements. When an error occurs, a supervision alarm is generated based on the criteria you have configured. The configured supervision instances are stored in the preset ProDiag function block. You can use the automatically generated ProDiag FBs or create and configure your own ProDiag FBs.

Advantages

ProDiag enables you to configure supervisions and monitor your plant without changing the user program code.

You perform plant diagnostics on your HMI device. The data is automatically synchronized in order to keep the display on your HMI device always up-to-date.

Requirements and licensing

Introduction

You configure the ProDiag supervisions in TIA Portal with STEP 7 and create the screen objects for monitoring and diagnostics with WinCC. You need a license to use the ProDiag functionality and the corresponding screen objects.

Software requirements

To configure ProDiag supervisions, you need the following products:

- TIA Portal STEP 7 Professional
- WinCC Unified

Hardware requirements

ProDiag functionality is available for CPUs of the S7-1500 series with firmware version 2.0 or higher.

The objects for the supervision and diagnostics of plants are available for the following HMI devices:

- WinCC Unified

Note

Objects for supervision and diagnostics of plants can be used under the "Full access" and "Read access" protection levels configured in the CPU.

ProDiag objects under the "HMI access" and "No access" protection levels cannot be used.

Licensing of ProDiag supervisions

The number of ProDiag monitors that you configure with STEP 7 is licensed. You do not need a license for the first 25 supervisions, licenses must be used for additional supervisions.

Number of supervisions	**<= 25**	**<= 250**	**<= 500**	**<= 750**	**<= 1000**	**> 1000**
Number of licenses	None	1	2	3	4	5

Licensing of ProjDiag objects

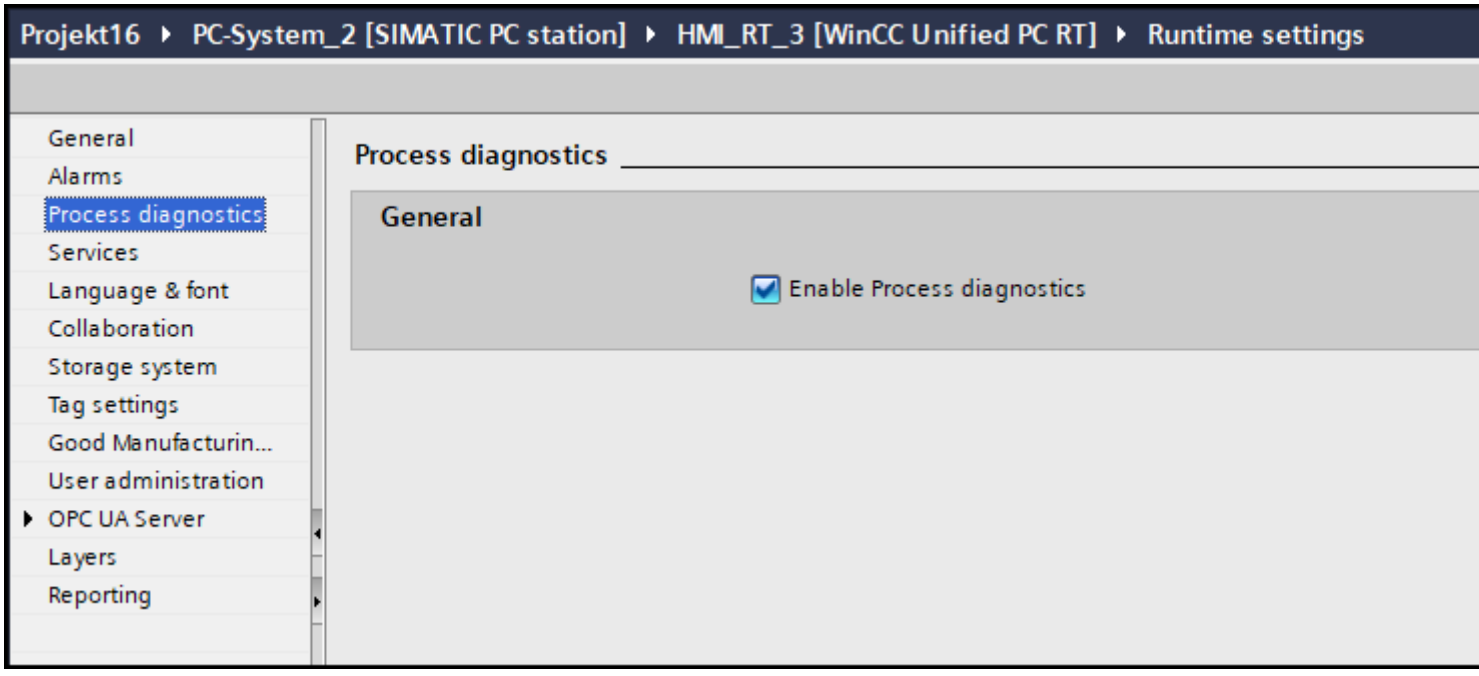
To use the objects for the diagnostics and supervision in conjunction with the ProDiag supervision in your program, you need a ProDiag license, specifically the WinCC Unified Runtime license.

Enable process diagnostics

To activate process diagnostics on an HMI device, follow these steps:

1. Open the "Runtime settings" of the HMI device in the project tree.
2. Under Process diagnostics, select the "Enable process diagnostics" option.

The display of process diagnostic alarms is enabled in runtime.



Objects for the supervision and diagnostics of plants

Introduction

WinCC offers the following objects for displaying the current monitoring status and for fault diagnostics in the program code:

- GRAPH overview
- PLC code view

GRAPH overview

The "GRAPH overview" object is used to display the current program status for executed steps of the GRAPH sequencer.

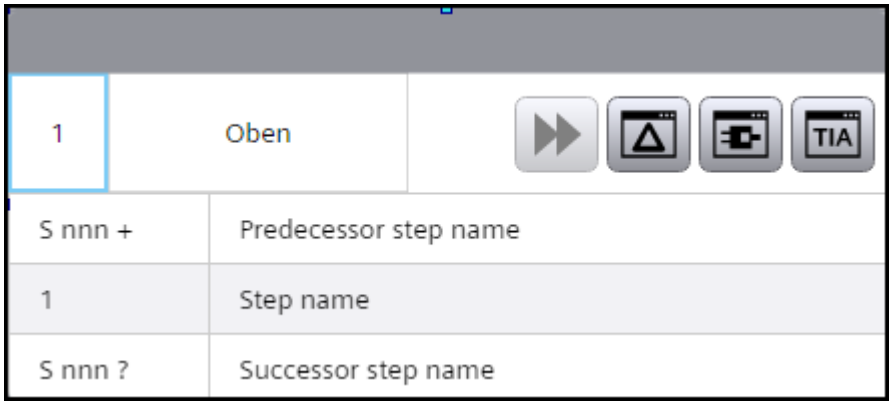
PLC code view

The "PLC code viewer" object is used to display the current program status of user programs that have been programmed in the GRAPH programming language.

GRAPH overview

Use

The "GRAPH Overview" object is used to display the current program status for executed steps of the GRAPH sequencer. Errors during execution of a program are displayed directly at the corresponding step.



The following information is displayed in the "GRAPH Overview" object:

- Name and status of the function block
- Status of initial and simultaneous steps
- Number and name of the first step currently executed step
- Operating mode for running the GRAPH sequencer

WinCC supports the display of step names for the GRAPH blocks in multiple languages starting from Version 6.0. The step names will then be displayed in the selected Runtime language following a language changeover in Runtime. If the selected language is not available in the GRAPH block, the names are displayed in the default language (English).

Note

Device dependency of the "GRAPH Overview" object

The "GRAPH overview" object is available for Unified PC.

Note

Requirement for display in GRAPH overview

For the display of the program status of an S7 GRAPH instance data block in the "GRAPH overview" object to be possible, the instance-specific properties of the block must be set as "Visible in HMI" and "Accessible from HMI".

Layout

In the Inspector window, you customize the position, style, colors and font types of the object. You can adapt the following properties in particular:

- Assigned GRAPH DB tag
- Buttons of the toolbar

Operating mode

Four operating modes are available for running the GRAPH sequence:

- AUTO (default setting) - Automatically switches to the next step when the transition is fulfilled.
- TAP - Automatically switches to the next step when the transition is fulfilled and there is an edge change from "0" to "1" at the T_PUSH parameter.
- TOP - Automatically switches to the next step when the transition is fulfilled or there is an edge change from "0" to "1" at the T_PUSH parameter.
- MAN - The next step is not automatically enabled when the transition is fulfilled. The steps can be selected and deselected manually.

Note

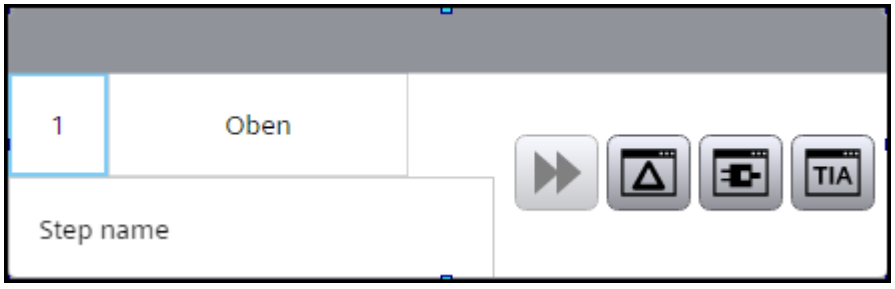
You set the operating mode by modifying the interface parameters of the GRAPH block in your control program.

In WinCC Unified Runtime, you have the option to customize the name for the operating mode that is displayed in the GRAPH overview.

Configuring a compact view

You can also configure a slim GRAPH overview without toolbar buttons and operating mode display.

To display a slim GRAPH overview in single-line compatibility mode, drag the control to the desired size.



Symbols

The symbols displayed in the GRAPH overview are pre-defined:

Symbol	Name	Function
	Error	Indicates that an error has occurred during the execution of a step.
	Initial step	Indicates that the currently executing step is the first step in the GRAPH block.
	Simultaneous step	Shows that there are other simultaneous steps in the GRAPH block in addition to the current one.

Buttons

You specify the buttons that are displayed in the GRAPH overview under "Properties > Miscellaneous > Toolbar > Elements".

Button	Name	Function
	Next Step	Jumps to the next step in parallel step. When you get to the last step, you can jump back to the first step.
	Jump to Alarm Control	Opens the configured alarm view with the error alarm in WinCC Unified. The button is intended to be populated with appropriate system functions/ scripts.
	Jump To PLC Code Viewer	Opens the configured PLC code view. The button is intended to be populated with appropriate system functions/ scripts. Ideally, use the "OpenViewerGraphFromOverview" system function.
	Jump to TIA Portal	Several system functions are available for opening the TIA Portal.

Configuring a GRAPH overview

Introduction

You can use the GRAPH overview to view the current program status for the executed steps of a GRAPH sequencer.

Requirement

- A PLC including a GRAPH instance data block has been created.
- GRAPH instance data block contains at least one tag which is visible in HMI and accessible from HMI.

  Note

  The process tag you are using for the GRAPH overview must be visible in HMI and accessible from HMI.

  To identify the tags of the GRAPH data block as visible and accessible for HMI, open the GRAPH function block, select the block in the work area, and select "Edit > Internal parameters visible/accessible from HMI" in the menu bar. Then compile the program blocks.

- An HMI device has been created.
- You have created a screen.
- The Inspector window is open.

Procedure

1. Drag-and-drop the GRAPH overview from the toolbox view into the configured screen.
2. In the Inspector window, click "Properties > Properties > Miscellaneous".
3. Open the selection button under "PLC Source > Tag".
   The "Add new object" dialog opens.
4. Select the corresponding PLC in the "Program blocks" folder.
5. Select the corresponding PLC tag of the GRAPH instance data block.

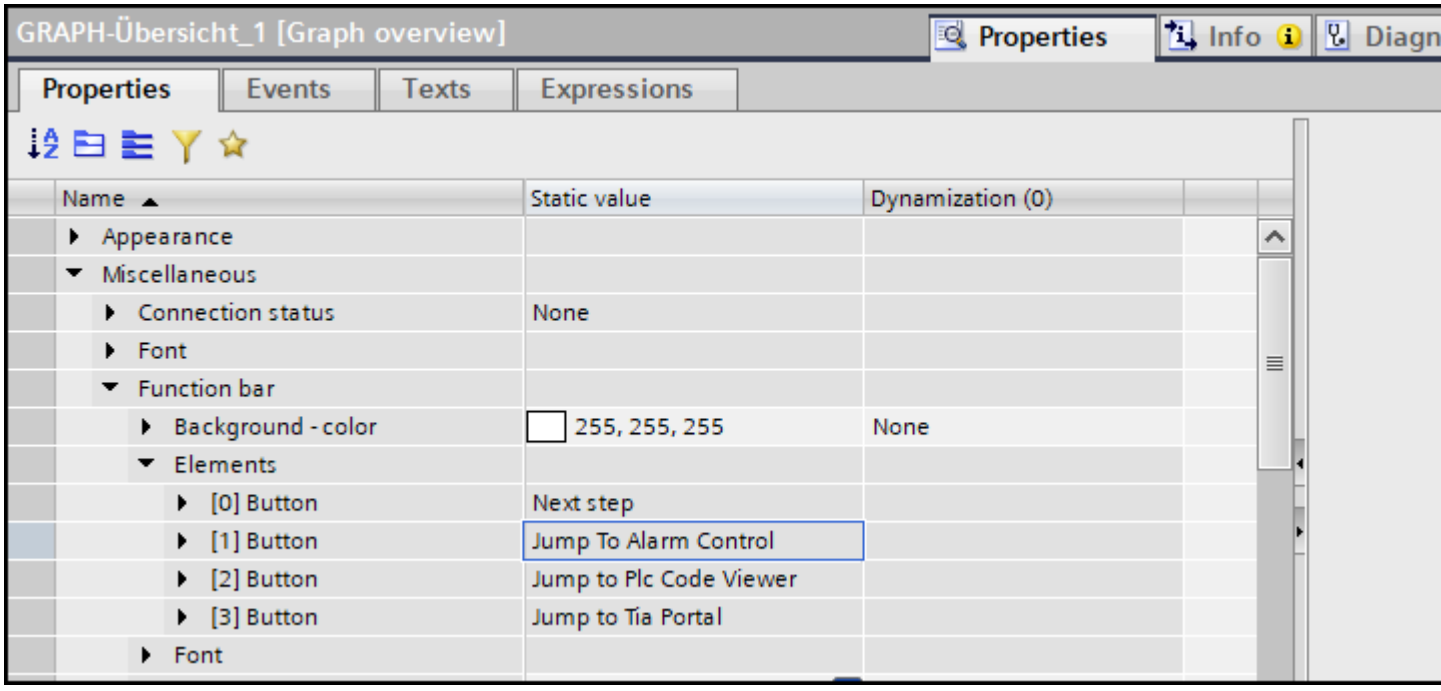
   Note

   If no connection was configured between the HMI device and the selected PLC, a connection is set up automatically.

   In addition, an HMI tag is created which is connected to the PLC tag.

6. To display the GRAPH overview in compatibility mode without toolbar buttons and operating mode display, drag the control to the desired size, whereby several basic views are possible.

7. Under "Properties > Properties > Miscellaneous > Toolbar > Elements", specify the buttons to be displayed in the object.



8. Under "Properties > Events" you can assign system functions or scripts to the buttons in the GRAPH overview in order to jump to the alarm control and the PLC code display in runtime and to open the TIA Portal.

Result

The GRAPH overview is inserted in the screen. The current status of the GRAPH step sequence is displayed in Runtime.

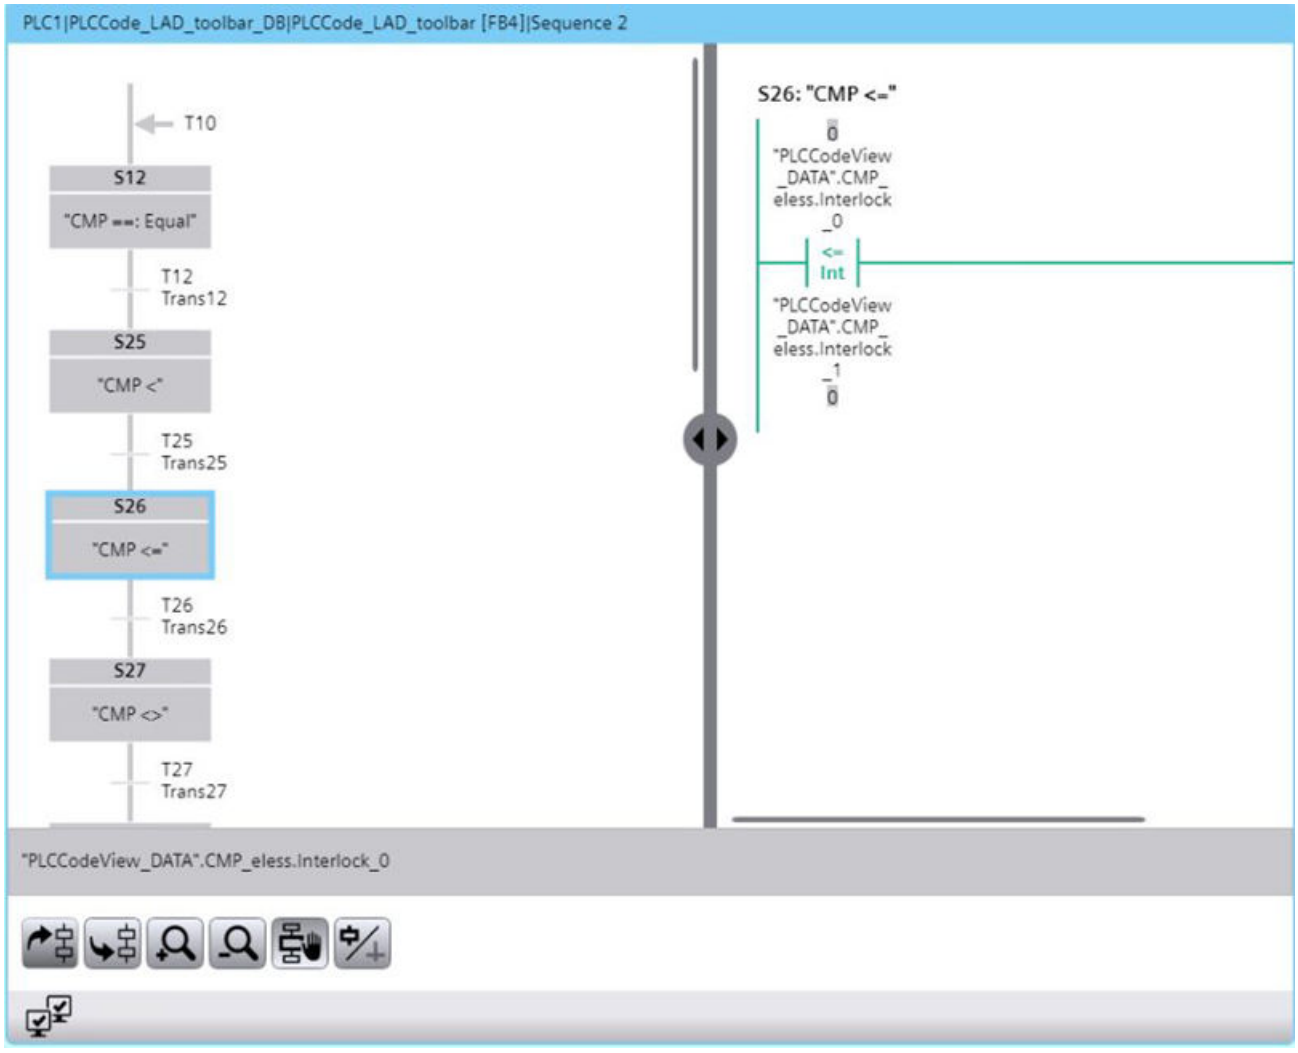
PLC code view

Use

The "PLC code viewer" object is used to display the current program status of user programs that have been programmed in the GRAPH programming language.

In the PLC code view, you display various items of information about the user program:

- Information area
- Toolbar
- Detail view
- Transition/Interlock view



Information area

The information area shows the GRAPH sequence in the left area and the details, e.g. for the step or for the transition, in the right area.

Toolbar

The toolbar shows information about the first or the selected icon.

Buttons of the toolbar

The table below shows the buttons on the toolbar and their meaning.

Operating element	Description	Function
	"Previous network"	Navigates to the previous network.
	"Next network"	Navigates to the next network.
	"Zoom in"	Enlarges the information area.
	"Zoom out"	Reduces the information area.
	"Step mode"	Switches between manual and automatic step selection for the active step.
	"Transition or Interlock"	Switches between the transition and interlock networks.

Configuring the PLC code view

Introduction

To display the PLC program networks in the GRAPH programming language in Runtime, insert a PLC code viewer control into your project.

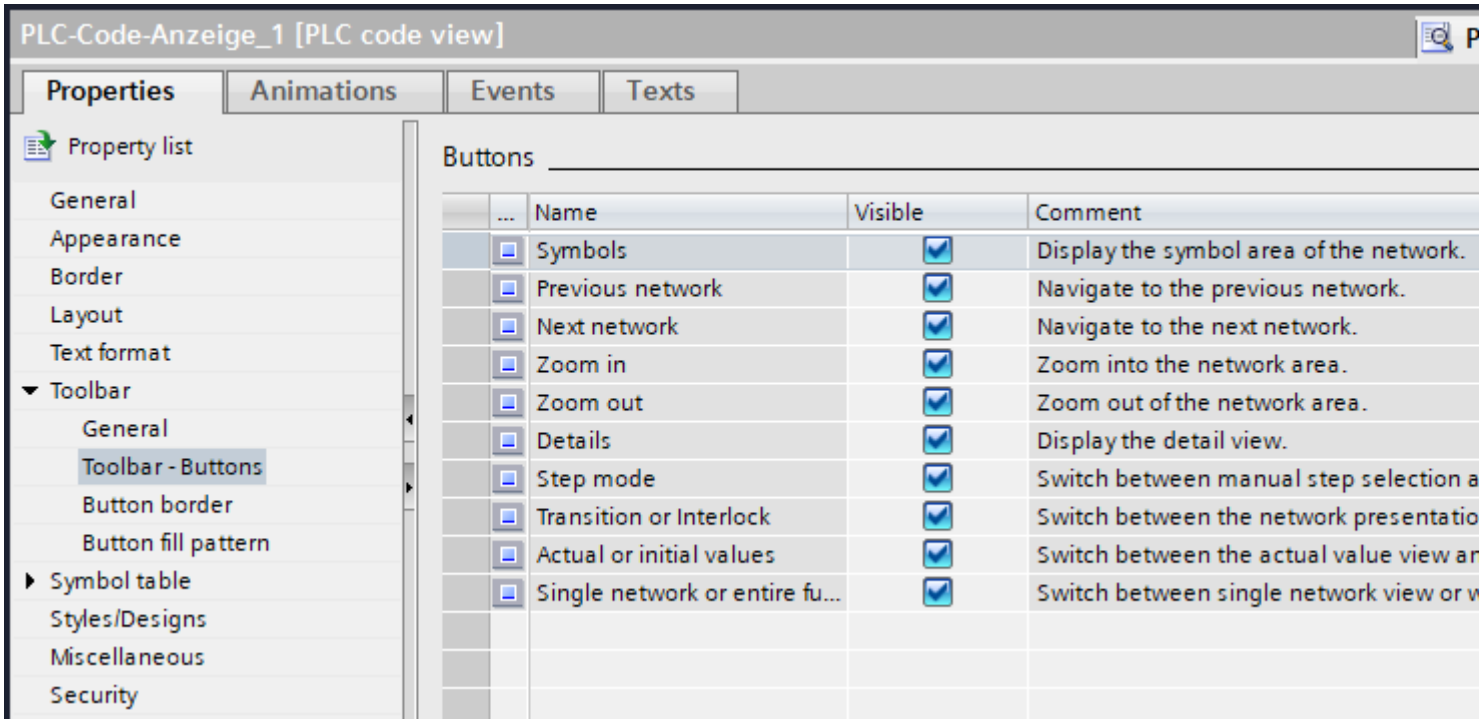
Requirement

- At least one PLC has been created.
- An HMI device has been created.
- An HMI connection has been established between the controller and HMI device.
- The system diagnostics is activated on all devices
- You have created a screen.

Procedure

1. Drag-and-drop the PLC code view from the toolbox view.
2. In the Inspector window, click "Properties > Properties > Toolbar".

3. Select the buttons that you require in Runtime, for example: Next network, Previous network, Step mode.



4. Select an authorization for operator input in "Properties > Properties > Security".

Result

The PLC code view is inserted in the screen. In Runtime, PLC user programs that are programmed in the GRAPH programming language can be displayed.

You can populate the PLC code viewer using system functions, e.g. jump from the GRAPH overview, or you can select the corresponding parameters directly.

17.3.5 Elements

17.3.5.1 Overview of elements

Operable elements are available in process pictures in Runtime.

The following elements are available depending on the configured access rights:

Icon	Element	Brief description
	Bar	Represents tags graphically. The bar graph can be labeled with a value scale.
	I/O field	Used for entry and display of process values.
	Symbolic I/O field	A drop-down list with texts or graphics for display and input in runtime.

Icon	Element	Brief description
	Check box	Used for display and selection of multiple options.
	List box	Used for display and selection of multiple list entries.
	Radio button	Used for display and selection of various options of which only one can be selected.
	Switch	Used for toggling between two predefined states.
	Button	Executes a configured function.
	Slider	Used for monitoring and changing process values within a defined range and adjusts them. By adjusting the slider, you intervene in the process and correct the displayed process value.
	Clock	Used for display of date and time.
	Gauge	Represents numerical values in the form of an analog gauge. For example, it can be seen at a glance whether the boiler pressure is in the normal range.

17.3.5.2 Using elements

Bar

Application

The tags are displayed graphically with the "Bar" object. The bar graph can be labeled with a value scale.

Layout

The settings for the position, geometry, style, colors and fonts of the object are made during configuration.

In particular, the following properties are changed:

- Color transition: Specifies the change in color display when limit values are exceeded.
- Limit marking: Displays the configured limit value as an arrow.
- Bar segments: Defines the gradations on the bar scale.
- Scale gradation: Defines the position of the zero point on a bar scale.

If the object falls below a certain size in the light or dark style, it is automatically displayed in compact mode.

Color transition

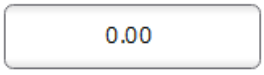
The display of the color change is specified during configuration.

Color transition	Description
"Segmented"	If a particular limit was reached, the bar changes color segment by segment. With segmented display, for example, the limits exceeded by the displayed value are visualized.
"Entire bar"	If a particular limit was reached, the entire bar changes color.

IO field

Use

The "I/O field" object is used to enter and display process values.



Layout

The settings for the position, geometry, style, color and fonts of the object are made during configuration.

In particular, the following properties are changed:

- Mode: Specifies the behavior of the object in Runtime.
- Display format: Specifies the display format in the I/O field for input and output of values.
- Hidden input: Specifies whether the input value is displayed normally or encrypted during input.

Note

Reports

In reports, I/O fields only output data. "Output" mode is preset. Properties for configuring input are not available, e.g. "hidden input".

Mode

The behavior of the I/O field is specified during configuration.

Mode	Description
"Input/output"	Values can be input and output in the I/O field.
"Output"	The I/O field is used for the output of values only.

Layout

The "display format" for the input and output of values is specified during configuration.

Layout	
"Binary"	Input and output of values in binary form
"Date"	Input and output of date information. The format depends on the language setting on the HMI device.
"Date/time"	Input and output of date and time information. The format depends on the language setting on the HMI device.
"Decimal"	Input and output of values in decimal form
"Hexadecimal"	Input and output of values in hexadecimal form
"Time"	Input and output of times. The format depends on the language setting on the HMI device.
"Character string"	Input and output of character strings.

Hidden input

In Runtime the input can be displayed normally or encrypted, for example for hidden input of a password. A "*" is displayed for every character during hidden input. The data format of the value entered cannot be recognized.

Avoid overlaps in output fields

If several I/O fields are configured as output fields with a transparent background in a screen, these I/O fields may overlap. The transparent part of the one field covers the digits of the other field. This may cause display problems. In order to avoid such overlaps, the border of the I/O fields must be set to zero during configuration.

Limits

During configuration, colors can be specified for the values that exceed or fall below limits.

When there is a limit violation, the background color of the I/O field changes according to the configuration, even if the I/O field is in input mode.

A limit range can also be defined for the input in the I/O field for the configuration.

If you enter a numeric value outside this limit, it is not applied; for example, 80 with a limit of 78. In this case, a system alarm is generated on the HMI device if an alarm window is configured. The original value is displayed again.

Decimal places for numerical values

The number of decimal places can be specified for a numerical input field during configuration. The number of decimal places is checked when you enter a value in this type of I/O field. Decimal places in excess of the limit are ignored. Empty decimal places are filled with "0".

In the exponential display, the displayed numerical value is represented with a maximum precision of nine decimal places.

Setting an LTime PLC tag via HMI

S7-1500 tags with data type LTime have the unit nanoseconds (ns). IO fields that are linked with such a PLC tag have the unit 100 ns.

HMI user inputs to the I/O field are converted to ns when the value is sent to the PLC.

Note

MAX_SAFE_INTEGER

Depending on the JavaScript engine of the web client, the actual value may lose accuracy during communication between the HMI device and the controller due to rounding if it is outside the value range of MAX_SAFE_INTEGER.

Additional information on MAX_SAFE_INTEGER can be found here (https://developer.mozilla.org/en-US/docs/Web/JavaScript/Reference/Global_Objects/Number/MAX_SAFE_INTEGER).

Behavior when switching between input fields

When you change from one input field to another within a screen due to an operator input and the on-screen keyboard appears, the "Exit field" event is not immediately triggered for the previous field. Rather, it is only triggered after the on-screen keyboard is closed.

No events during the input

While an I/O field is in input mode, no events are transmitted to the server for the I/O field.

Terminate the input mode with Enter or Esc so that the events configured for the I/O field in engineering take effect again.

Symbolic IO field

Use

The "Symbolic I/O field" list is used for displaying texts and graphics in runtime as well as text input, if configured.

The displayed texts or graphics are assigned to the potential tag values.

Note

Selecting the default entry is not possible in runtime.

Layout

The settings for the position, geometry, style, color and fonts of the object are made during configuration.

In particular, the following properties are changed:

- "Mode": Specifies the response of the object in runtime.
- "Resource list": Specifies the text or graphic list that will be associated with the object.

Mode

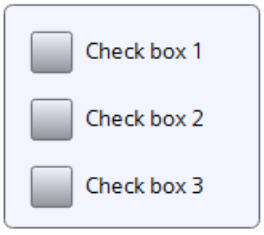
The behavior of the symbolic I/O field is specified during configuration.

Mode	Description
"Output"	The symbolic IO field is used for the output of values.
"Input/output"	The symbolic IO field is used for the input and output of values.

Check box

Application

You use the "Checkbox" object to select multiple options. Checkboxes can be activated by default so that the user changes the default values only as required. Multiple options can be selected if the corresponding properties are dynamized.



Layout

The settings for the position, geometry, style, color and fonts of the object are made during configuration.

In particular, the following properties are changed:

- Number of the checkboxes: Defines the number of options.
- Selection of the checkboxes: Defines which options are displayed as activated by default.

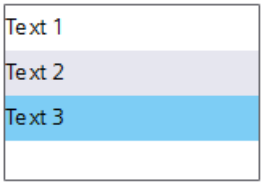
Default setting of the checkboxes

Each option is represented by a bit in a 32-bit word. To activate a field, the corresponding bit must have the value "1". The 32-bit word contains the information for all options of the checkbox list. The value of the "Presetting enabled" property is specified in hexadecimal format.

List box

Application

You use the "List box" object to present and select multiple list entries. List entries are selected by default so that the default setting can be changed only when necessary. If the list box is larger than the selection rectangle, WinCC automatically adds a scroll bar to the right margin.



Layout

The settings for the position, geometry, style, color and fonts of the object are made during configuration.

In particular, the following properties are changed:

- Number of entries: Defines the number of list entries.
- Selection of entries: Defines which entry is displayed as activated by default.

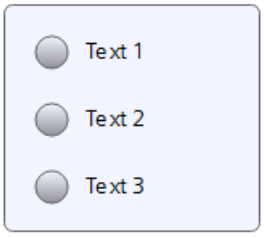
Default setting of the list boxes

Each option is represented by a bit in a 32-bit word. To activate a field, the corresponding bit must have the value "1". The 32-bit word contains the information for all texts of the list of list boxes. The value of the "Selected fields" property is given in hexadecimal notation.

Option buttons

Application

You use the "Option button" object for selection of various options. Options are selected by default so that the default setting can be changed only when necessary. Only one option can be selected if the corresponding property is dynamized.



Layout

The settings for the position, geometry, style, color and fonts of the object are made during configuration.

In particular, the following properties are changed:

- Number of fields
- Selection of the fields: Specifies which fields are displayed as activated.

Switch

Application

With the "Switch" object you switch between two predefined states. The current state of the "Switch" object is visualized with either a label or a graphic.

Layout

The settings for the position, geometry, style, color and fonts of the object are made during configuration.

In particular, the following property is changed:

- Type: Defines the graphic representation of the object.

Type

The display of the switch is specified during configuration.

Type	Description
"Switch"	The two states of the "Switch" are displayed in the form of a switch. The position of the switch indicates the current state. The switch is switched by moving it.
"Switch with text"	The switch is shown as a button. The current state is visualized with a label. The switch is switched by clicking the button.
"Switch with graphic"	The switch is shown as a button. The current state is visualized with a graphic. The switch is switched by clicking the button.

Button

Use

With the "Button" object, you execute a configured function.

Layout

The settings for the position, geometry, style, color and font of the object are made during configuration.

In particular, the following properties are changed:

- Mode: Defines the graphic representation of the object.
- Text / Graphic: Defines whether the Graphic view is static or dynamic.
- Define hotkey: Defines a key, or shortcut that the operator can use to actuate the button.

  Note

  You can only define a hotkey for HMI devices with keys.

Mode

The display of the button is specified during configuration.

Mode	Description
"Invisible"	The button is not visible.
"Text"	The button is displayed with text. This text explains the function of the button.
"Graphic"	The button is displayed with a graphic. This graphic represents the function of the button.
"Graphic or text"	The button is displayed with text or graphics. If the graphic cannot be displayed, the corresponding text is displayed.
"Graphic and text"	The button is displayed with text and graphic.

Different options are available depending on the device.

Text / Graphic

Depending on the "Mode" property, the display can be specified as a static or dynamic display. The display is specified during configuration.

You can, for example, select the following options for the "Graphic" or "Text" type.

Type	Option	Description
"Graphic"	"Graphic"	With "Graphic when button "not pressed"", a graphic is specified that is displayed in the button for the "OFF" state. When "Graphic when button "pressed"" is selected, a graphic for the "ON" state can be entered.
	"Graphics list"	The graphic in the button depends on the state. The corresponding entry from the graphics list is displayed depending on the state.
"Text"	"Text"	With "Text when button "not pressed"", a text is specified that is displayed in the button for the "OFF" state. When "Text when button "pressed"" is selected, a text for the "ON" state can be entered.
	"Text list"	The text in the button depends on the state. The entry from the text list corresponding to the state is displayed.

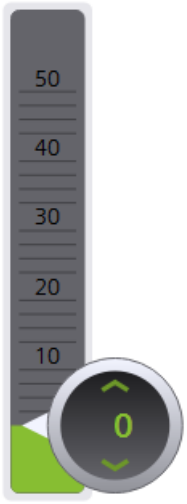
Hotkey

A key or key combination that the operator can use to actuate the button can be defined during configuration.

Slider

Use

Process values are monitored and adapted within a defined range with the "Slider" object. The monitored range is visualized in the form of a slider. By adjusting the slider, you intervene in the process and correct the displayed process value.



Layout

The settings for the position, geometry, style, color and fonts of the object are made during configuration.

In particular, the following properties are changed:

- Maximum Value and Minimum Value: Specifies the top and bottom values of the scale.
- Display current value: Specifies whether the current position of the controller appears below the slider.
- Display of bars: The sliders above and below the bar can be hidden.

If the object falls below a certain size in the light or dark style, it is automatically displayed in compact mode.

Limits/ranges

You can represent limits and ranges in different colors. The colors are defined during configuration.

Note

If the "Show ranges from tag" option is selected, up to five ranges can be displayed in a slider. The values of the ranges are specified using a process tag. The values for the ranges are defined with a process tag that is connected to the screen object.

The option "Show ranges from tag" is available for Comfort Panels, KTP Mobile Panels and RT Advanced.

Behavior during operation

The displayed value on the slider control may deviate from the actual value of the associated tag in the following circumstances:

- The value range (minimum and maximum value) configured for the slider control does not correspond to the configured limits for the slider control tag.
- An invalid password has been entered for a password-protected slider control.

Clock

Application

The "Clock" object displays the date and time.

By default, the "Clock" object displays the date and time of the client.

If the "Process value" property of the clock is connected to a DateTime tag, the clock uses the tag value as a start value and continues counting. When the tag value is changed the time is synchronized and continues counting from the new value.

Note

Static display of a date-time value

If the image is supposed to display a static time of day, link a tag of the type DateTime with an I/O field.

Layout

The settings for the position, geometry, style, color and fonts of the object are made during configuration.

In particular, the following properties are adapted:

- Analog display: Specifies whether the clock is shown as an analog clock or digital clock.
- Display clock dial: Specifies whether hour marks of the analog clock will be displayed.
- Width and length of hands: Specifies the width and length of the hands.

If the object falls below a certain size in the light or dark style, it is automatically displayed in compact mode.

Gauge

Use

The "Gauge" object shows numeric values in the form of an analog gauge. For example, it can be seen at a glance whether the boiler pressure is in the normal range.

Note

The gauge is for display only and cannot be controlled by the operator.

Layout

The settings for the position, geometry, style, color and fonts of the object are made during configuration.

In particular, the following properties are changed:

- Display peak value: Specifies whether the actual measuring range is indicated with a peak indicator.
- Maximum Value and Minimum Value: Specifies the top and bottom values of the scale.
- Start value of the danger range and start value of the warning range: Specifies the scale value from which the danger range and the warning range start.
- Display normal range: Specifies whether the normal range is shown in color on the scale.
- Color of individual ranges: Different operating modes, such as normal range, warning range and danger range, are shown in different colors so that the operator can distinguish them easily.

If the object falls below a certain size in the light or dark style, it is automatically displayed in compact mode.

Note

The use of many differently sized "Gauge" objects can reduce the performance in Runtime. With "Gauge", avoid minimally different heights and widths, for example, 48 pixels, 49 pixels, 51 pixels, etc. Use the same sizes instead.

Display peak value

The "Display peak value" property can be used to enable a marker function for the maximum and minimum pointer movement in Runtime. The actual measuring range is shown with a min/max pointer.

Color of individual ranges

The normal range, danger range and warning range can be displayed in different colors. The colors are defined during configuration.

Note

If the "Show ranges from tag" option is selected, up to five ranges can be displayed in the gauge. The values of the ranges are specified using a process tag. The values for the ranges are defined with a process tag that is connected to the screen object.

The option "Show ranges from tag" is available for Comfort Panels, KTP Mobile Panels and RT Advanced.

17.3.6 Basic objects

In addition to controls and elements, HMI screens contain basic objects such as circles, polygons or text boxes. Basic objects are often used for design purposes, but can also provide information about the process.

Dynamically configured basic objects react to changes in the process or to operator actions. Example: In engineering, a text box is linked to a text list that defines text entries for the value range of a tag. In Runtime, the text box always shows the text assigned to the current tag value. When the tag changes its value, the content of the text box changes.

Overview of basic objects

Depending on the configuration, screens can contain the following basic objects:

- Line
- Polyline
- Polygon
- Ellipse
- Ellipse segment
- Circle segment
- Elliptical arc
- Circular arc
- Circle
- Rectangle
- Text box
- Graphic view

Process values in text fields

If a text box has been connected to a tag in engineering, the text box shows the process value of the tag in runtime.

If the text box was connected to a tag and a text list, the text box shows the text list entry that corresponds to the tag value.

Note

If no default value is assigned to the text list and the tag value is outside the defined value range of the text list, the last valid process value displayed by the text box is output.

17.3.7 Popup window

Popup windows are freely movable windows that open when an event configured in the engineering system occurs. They show, for example, additional information on a partial area of the process image.

You close a popup window using the button in the top right corner of the popup window.

Example

Runtime shows a screen with an overview graphic for a pump and its valves.

Configuration in the engineering system

A faceplate instance was positioned on the screen for each valve, which is displayed by the graphic of the valve. The faceplate instances have a script that opens an additional faceplate instance in a popup window in Runtime. This second instance shows detailed information on the valve as well as input fields.

Behavior in Runtime

When you click on a valve in the overview graphic in the screen, a popup window opens. In the popup window, you can check the state of the valve and edit the valve using the input fields.

17.3.8 Tests and error analysis

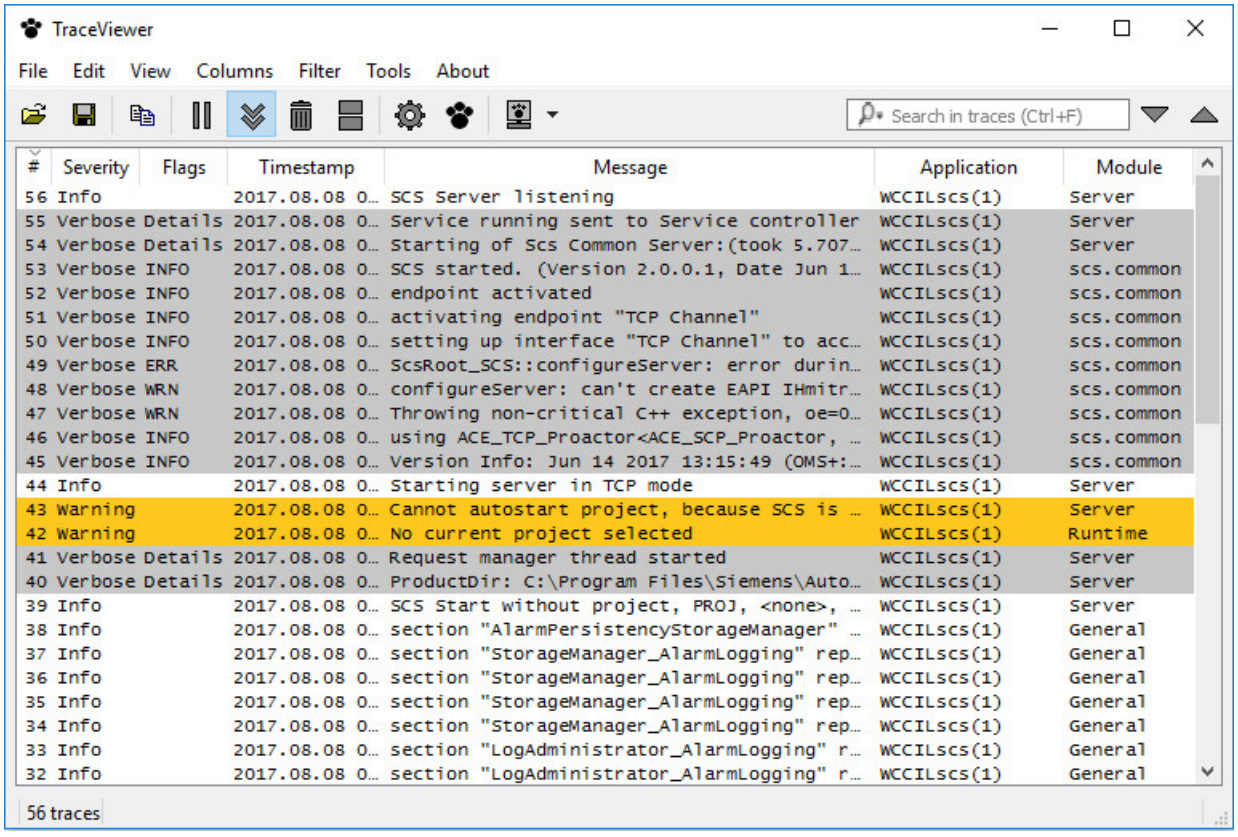
17.3.8.1 Trace logs for function calls and tag values

WinCC Unified provides trace logging for error analysis. Tag values and function calls can be logged for test purposes and for troubleshooting with the trace.

All trace outputs with "Fatal", "Error" or "Warning" severity are stored in LOG files (.log) in the directory "%ProgramData%\Siemens\Automation\Logfiles\WinCC_Unified_SCADA_Vxx". In case of problems you must send these files to SIEMENS Customer Support.

TraceViewer

The LOG files can be viewed with the TraceViewer. It is located in the installation directory of WinCC Unified under "WinCCUnified\bin". To open the Trace Viewer start the file "RTILtraceViewer.exe".



17.3.8.2 Debugging scripts

Basics of debugging

Introduction

For example, you can use a debugger to test whether correct values are being transferred to tags and whether abort conditions are being correctly implemented. Check the following in the debugger:

- Source code of functions
- Function sequence
- Values

Note

Your code is displayed in the debugger but is write-protected.

Basic procedure

To find an error, check the script with the debugger.

The following options are available for your support:

- Setting breakpoints
- Step-by-step execution
- Viewing values parallel to execution of the script

You do not edit the code of your scripts directly in the debugger. When you find an error, follow these steps:

1. Correct the error in the engineering system.
2. Compile the changed code.
3. Load the runtime.
4. Update the debugger.

Design and function of the debugger

Google Chrome provides the user interface of the debugger. Not all functions of the user interface of the debugger are relevant for debugging WinCC Unified Scripts. Only the functions that are needed to debug scripts in WinCC Unified are explained below.

You can find more information on Chrome DevTools under: https://developers.google.com/web/tools/chrome-devtools/.

The debugger is divided into two areas:

- Debugger for screens
- Debugger for jobs

With the debugger for screens you view scripts at screens and screen objects. With the debugger for jobs, you view scripts that you have configured in the Scheduler.

Start page of the debugger

After the debugger has been started, its start page is displayed.

The available contents differ depending on the selected area.

On the start page of the debugger for screens you can see two different contexts:

- Dynamizations (e.g. "UMCadmin@192.168.116.144 VCS_1 Dynamics")
- Events (e.g. "UMCadmin@192.168.116.144 VCS_1 Events")

The name of the contexts is composed as follows:

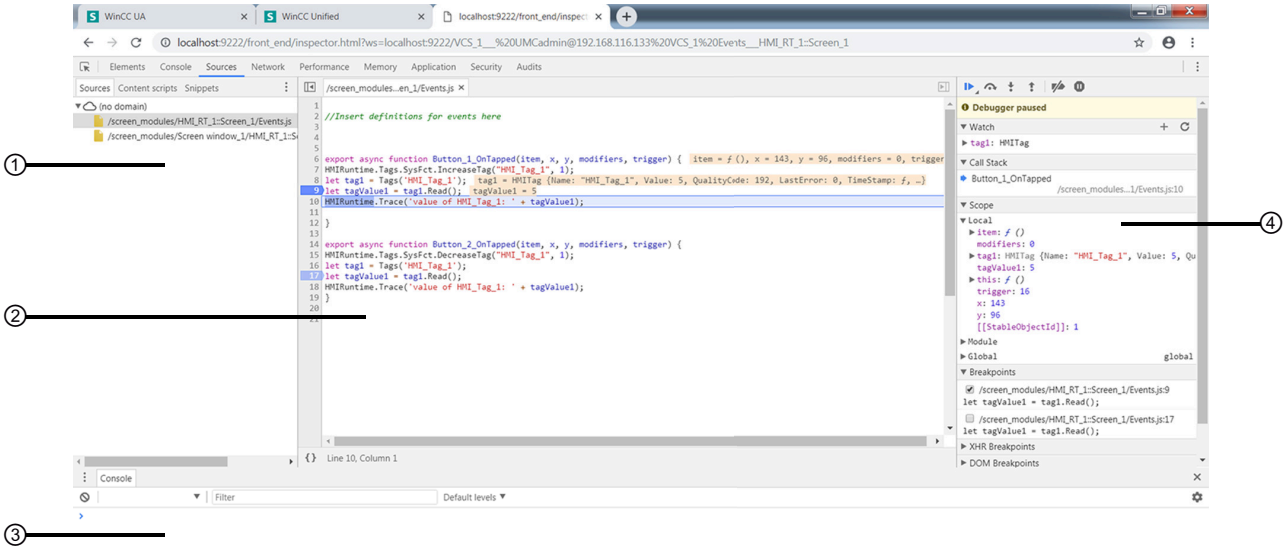
- UMCadmin: User name
- 192.168.116.144: IP address of the computer
- VCS: Name of the graphic component
- _1: Number of the open client
- Events/Dynamics: Scripts at events or dynamizations

Note

A client corresponds to a tab in Google Chrome in which the runtime is open. When you have opened runtime in multiple tabs, multiple clients are used. The client opened first is given the number 1. Numbering is reset when the runtime is restarted.

On the start page of the debugger for jobs you can see the context "JobsExecution".

User interface of the debugger



① Navigation area
② Code display area
③ Console
④ Debugging area

Navigation area

In the navigation area, the available contents for the screen shown in runtime are displayed in groups. The available groups vary depending on the use of scripts and functions.

Groups in the debugger for screens

The debugger for screens can contain the following groups in the dynamizations context:

- A group for scripts that were configured for dynamizations.
- One group per screen window in which scripts were configured for dynamizations.

The debugger for screens can contain the following groups in the events context:

- A group for scripts that were configured for events.
- One group for functions that were configured for events using the function list.
- One group per screen window in which scripts were configured for events.
- One group per screen window in which functions were configured for events using the function list.

Groups in the debugger for jobs

The debugger for jobs can contain the following groups:

- A group for scripts that were configured for tasks.
- One group for functions that were configured for tasks using the function list.

Code display area

Your code is displayed in the code display area. The rows are numbered.

Debugging area

The debugging area offers the following relevant options for WinCC Unified:

- Toolbar: Control for executing the script
- "Watch": Display of values
- "Callstack": Display of the current call stack
- "Scope": Available local values ("Local"), functions ("Module") and global values ("Global"),
- "Breakpoints": List of set breakpoints

Enabling the debugger

Requirement

- SIMATIC Runtime Manager is installed.
- The logged-on user belongs to the Windows user group "SIMATIC HMI".

Note

The debugger is only available locally.

Remote access from the debugger to other devices is not possible.

Procedure

The debugger is disabled by default.

Note

The debugger should be disabled in production operation, as using the debugger can endanger system stability and security. Actions can accumulate if the debugger is, for example, at a breakpoint for a long time or the screen is not refreshed.

To enable the debugger, follow these steps:

1. Start the SIMATIC Runtime Manager application.
2. Click the  button in the toolbar.
3. Switch to the "Scripts Debugger" tab.
4. To enable the debugger for screens, select the "Enable" check box in the "Screen debugger" area.
5. To enable the debugger for scheduled tasks, select the "Enable" check box in the "Scheduler debugger" area.
6. Assign an available port number to the debugger for screens (default port number: 9222).
7. Assign an available port number to the debugger for jobs (default port number: 9224).
8. Confirm your entries.

Note

Start Runtime after enabling the debugger.

Starting the debugger

Requirement

- Google Chrome (as of version 70) is installed.
- A project is opened in runtime.
- The debugger was activated in SIMATIC Runtime Manager.

Note

The debugger is only available locally.

Remote access from the debugger to other devices is not possible.

Procedure

1. In a new tab, call up the URL chrome://inspect in Google Chrome.
2. The home page of the Chrome DevTools is loaded in the tab.
3. Click "Devices".
4. Select the "Discover network targets" check box.
5. Click "Configure".
6. In the "Target discovery settings" dialog box, enter one of the following strings:
   - `127.0.0.1:<Port number>`
   - `localhost:<Port number>`

   Use the port entered for the Script Debugger in SIMATIC Runtime Manager.
7. Press <Enter>.
8. Click "Done".
9. Under "Remote Target", click "inspect" for the desired target.
   The DevTools open in a separate window with the selected target.
10. In the DevTools, select "Sources".
    The debugger is displayed.
11. Click "Toggle screencast".
12. In the navigation area under "Page", select the desired script module.

Updating the debugger

The debugger must be updated:

- After starting a new project
- After restarting a running project, for example, because you have reloaded the project in engineering with "Download to device > Software (all)".
- After a screen change in Runtime

The connection to the debugger is lost in each case. Google Chrome therefore shows an error message and asks whether you want to restore the connection.

To restore the connection, proceed as follows:

1. Close the DevTools window.
2. On the DevTools start page under "Remote Target", click "inspect" again for the desired target.

Stopping the debugger

Exit the debugger by closing the DevTools window and, if necessary, the DevTools homepage.

This does not stop runtime.

Working with breakpoints

Set breakpoints to stop the execution of the script at certain points and thus localize errors step-by-step. Previously set breakpoints are still available after updating the debugger.

Requirement

- Runtime has started.
- The debugger has been started.
- The group you want to debug is selected.

Pause script

To pause the execution of a script, you have 2 options:

- To pause the script immediately, click the "Pause script execution" button while the script is being executed.
- Set a breakpoint in the desired line.
  The script pauses when a breakpoint is reached.

To pause a script at a breakpoint that is configured to an event, follow these steps:

1. Set a breakpoint in the script.
2. Trip the respective event in runtime.
   The script pauses at the breakpoint.

Setting breakpoints

You have several options to set a breakpoint in a line of the script:

- Click on the line number.
- Right-click the line number and select "Add Breakpoint".

All set breakpoints are displayed in the debugging area under "Breakpoints".

Linking breakpoints to conditions

To link a breakpoint to a condition, proceed as follows:

1. Open the shortcut menu of the relevant line.
2. Select the entry "Add conditional breakpoint".
   Execution of the script is stopped at the breakpoint when the condition is fulfilled.

Edit conditions as follows:

1. Open the shortcut menu of the relevant line.
2. Select the entry "Edit breakpoint...".

To prevent the script from pausing at a selected line, proceed as follows:

1. Open the shortcut menu of the respective line.
2. Select the entry "Never pause here".

Showing and hiding breakpoints

When you hide a breakpoint, its position is retained. The script then ignores the hidden breakpoint. When you need the breakpoint again, it can simply be shown.

In the debugging area, all breakpoints set in the selected group are displayed under "Breakpoints".

You have several options to show a breakpoint:

- Set the check mark in front of the relevant breakpoint in the debugging area under "Breakpoints".
- Alternatively, right-click the number of the respective line in the code display area and then select "Enable breakpoint".

You have several options to hide a breakpoint:

- Remove the check mark in front of the relevant breakpoint in debugging area under "Breakpoints".
- Alternatively, right-click the number of the respective line in the code display area and then select "Disable breakpoint".

To show or hide all breakpoints, follow these steps:

1. Open the shortcut menu in the debugging area under "Breakpoints".
2. Select "Enable all breakpoints" or "Disable all breakpoints"

Enabling and disabling breakpoints

You can enable or disable all breakpoints independent of showing or hiding individual breakpoints.

You have several options to enable or disable all breakpoints:

- Click on the  "Deactivate breaktpoints" button in the debugging area.
- Open the shortcut menu of a breakpoint in the debugging area and select "Activate breakpoints" or "Deactivate breakpoints".
- Press <Ctrl + F8>.

Deleting breakpoints

You have several options to delete a breakpoint:

- Click on the breakpoint in the code display area.
- Open the shortcut menu of the breakpoint in the code display area and select "Remove breakpoint".
- Open the shortcut menu in the debugging area under "Breakpoints" and select "Remove breakpoint"..

To delete breakpoints, the shortcut menu offers the following additional options in the debugging area under "Breakpoints":

- Delete all breakpoints ("Remove all breakpoints")
- Delete all breakpoints except the selected breakpoint ("Remove other breakpoints")

Step-by-step execution of scripts

Introduction

The following options are available to execute your script step-by-step:

- Execute script to the next breakpoint
- Force execution of a script
- Execute script to the next function call
- Jump into a function
- Jump out of a function
- Execute script up to a selected line
- Pause at Exceptions
- Use call stack

Requirement

- The group you want to debug is selected.
- The script pauses at a breakpoint.

Execute script to the next breakpoint

To pause the continuation of a script, you have several options:

- Click on the "Resume script execution" button in the debugging area.
- Press the <F8> key.
  The script is executed to the next breakpoint. If there is no other breakpoint, the script is executed completely.

Force execution of a script

To ignore the following breakpoints when resuming execution of a paused script, proceed as follows:

1. Click and hold down the "Resume script execution" button.
   The "Force script execution" button appears.
2. Move the mouse pointer to the "Force script execution" button while keeping the mouse button pressed.
3. Now release the mouse button.
   The script is executed to the end.

Execute script to the next function call

If a line with a breakpoint contains a function that you are not interested in, you can suppress the debugging of this function:

- Click on the "Step over next function call" button in the debugging area.
- Press the <F10> key.
  The function is executed without the script pausing within the function.

Jumping into a function

If the script pauses in a line containing a function that interests you, you can pause the script in that function:

- Click on the "Step into next function call" button in the debugging area.
- Press the <F11> key.
  The script pauses in the first line of the function.

Note

You can only jump into functions that you have defined yourself.

Jump out of a function

If the script pauses within a function that you are not interested in, you can suppress further debugging of this function:

- Click on the "Step out of current function" button in the debugging area.
- Press the key combination <Shift + F11>.

Note

You can only jump out of a function that you have defined yourself.

Execute script up to a selected line

To pause a paused script again at a selected line, proceeds as follows:

1. Right-click the number of the line in the code display area.
2. Select the entry "Continue to here".
   The script pauses at the selected line.

Pause at Exceptions

- To pause the script at Exceptions, click on the "Pause on exceptions" button in the debugging area.

Use call stack

- To jump into a function of the call stack, click on the corresponding entry under "Call Stack".

Note

You can only jump into functions that you have defined yourself.

Show values

Introduction

To identify errors in your script efficiently, have current values displayed while the script is being executed. This way you can view properties of objects or parameters of functions, for example. You can find additional information on objects and their properties under "WinCC Unified Object Model".

Requirements

- The group you want to debug is selected.
- The script pauses at a breakpoint.

Procedure

You view values by moving the mouse over the label in the code display area.

You also have the following options to view values:

- In the debugging area under "Scope"
- In the debugging area under "Watch"
- In the console

"Scope" area

All local values ("Local"), functions ("Module") and global values ("Global") that are defined at this time are displayed in the "Scope" area.

The values cannot be edited.

"Watch" area

In the "Watch" area, you view how values change in the course of a script.

The following buttons are available to you:

- "Add expression": Add a value
- "Refresh": Refresh the "Watch" area
- "Delete watch expression": Delete a value from the "Watch" area. Available when the mouse pointer is located above the respective value.

Console

The values available at the current time can be called in the console.

- You show or hide the console with <Esc>.

Call the current values in the console as follows:

1. Enter the name of a local or global value in the console.
2. Press <Enter>.

17.4 SIMATIC Runtime Manager

17.4.1 Functions in the SIMATIC Runtime Manager

Introduction

The SIMATIC Runtime Manager offers the following options for WinCC Unified PC:

- Use the project list to get an overview of the projects loaded into the Runtime and their properties.
  See The Runtime Manager user interface (Page 7493).
- Manually start and stop a project loaded into the Runtime.
  See Starting the project (Page 7495).
- Define a project that is started automatically when the HMI device starts up.
  See Selecting an autostart project (Page 7499).
- Restore log segments in Runtime and delete restored segments.
  See Restoring and deleting log segments (Page 7499).

- Load a project from an external storage medium into Runtime.
  See Adding a project (Page 7497).
- Make the following settings, if required:

Password	Enter the password that is used by the Runtime Manager for secure communication with Runtime.	See Enter password (Page 7500).
Autoscaling	Enable automatic adaptation of the HMI screens to the window size of the browser in which the Runtime project is displayed (autoscale).	See Setting general settings (Page 7501).
Language	Change the user interface language of SIMATIC Runtime Manager.	
Automatic login	Enable automatic login for a local web client of a Unified PC.	See Activating automatic login (Page 7502).
Start external processes	Enable the start of external processes from runtime.	See Allowing start of external processes (Page 7503).
OPC UA Export	Export the tags of the project running in Runtime into an XML file via the OPC UA server.	See Exporting tags via the OPC UA server (Page 7507).
User management	Enable the user administration of the project running in Runtime.	See Activating user management (Page 7508).
Certificates	Manage and distribute certificates of external communication partners and manage and distribute the root certificate of the Unified PC.	See Managing certificates (Page 7504).
Runtime script debugger	Configure and enable the Runtime script debugger (screen debugger and scheduler debugger).	See Setting the Runtime Script Debugger settings (Page 7509).

17.4.2 Start Runtime Manager

Requirement

WinCC Unified Runtime for PC is installed on the device.

Procedure

Double-click the desktop link created during the installation of WinCC Unified Runtime.

Alternatively, start the Runtime Manager from a file explorer by double-clicking the following file: "<Path to the Unified installation directory>\bin\SIMATICRuntimeManager.exe"

For example C:\Program Files\Siemens\Automation\WinCCUnified\bin\SIMATICRuntimeManager.exe

Note

Starting the Runtime Manager as administrator

Some settings under "Settings" require the Runtime Manager to be started as administrator. Right-click on the .exe and select "Run as administrator".

17.4.3 The Runtime Manager user interface

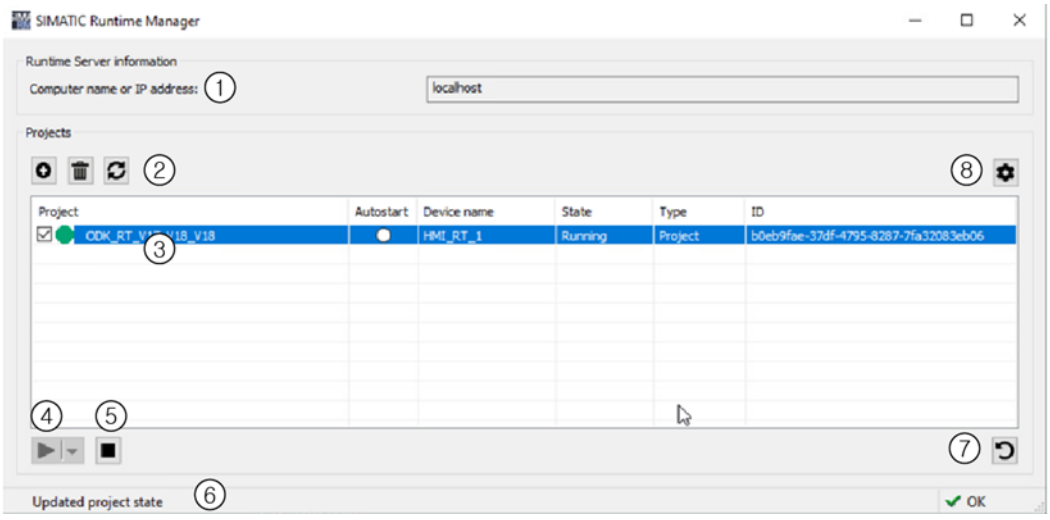
Note

User interface language

Runtime Manager starts with the language configured in the general settings. You can change the interface language. See also Setting general settings (Page 7501).

Structure

The Runtime Manager has the following structure:



① Information about the server on which the Runtime is installed
② Toolbar
③ Project list
④ Button to start the project is selected in the project list
⑤ Button to stop the project is selected in the project list
⑥ Information bar
⑦ "Restore/remove database segments for logs" button
⑧ "SIMATIC Runtime Manager settings" button

Toolbar

The toolbar has the following buttons:

Icon	Function
	Loads a project from an external storage medium into the Runtime.
	Deletes from the Runtime the project selected in the project list. The project folder and the log folders are deleted.
	Updates the project list.

Content of the project list.

The project list shows all projects loaded into the Runtime.

The list provides the following information on the projects:

Project details	Description
Project	Project name
Autostart	Indicates whether the "Autostart" option is enabled.
Device name	Device name
State	State of the associated Runtime service Possible status values: • Running • Partly running • Shutting down • Stopped • Unknown
Type	Type of the Runtime service Project: Runtime mode Simulation: Simulation mode
ID	Project-ID

17.4.4 Starting the project

Requirement

A project is loaded in runtime that does not have the "Running" state.

Start without reset

Proceed as follows to start the project in a state that existed before the last project stop:

1. Click on the project in the project list.
2. Click the "Start" button ▶|▾.
3. Select "Start".

Start with reset

Proceed as follows to start the project in a state that existed during the first project start:

1. Click on the project in the project list.
2. Click the "Start" button ▶|▾.
3. Select "Start with options".
4. Enable the options "Reset logging data" and/or "Reset Runtime data" in the "Start project options" dialog.
5. Click "Start".

"Partly running" status

If it is not possible to start the simulation or the Unified Runtime and the status of the project is displayed as "partly running", check the following:

- Does the user currently logged on in Runtime have sufficient rights? Is the user registered in the following Windows user groups:
  - PlcSimUsers
  - RTIL Tracing Users
  - Siemens TIA Engineer
  - SIMATIC HMI
  - SIMATIC HMI VIEWER
- Is the computer name no longer than 15 characters?
- Is the "OPC UA" activated in the Runtime settings and is a certificate is available?
- Is "Runtime Collaboration" enabled in the Runtime settings of a Unified Panel and is a certificate available?

Result

- The project is started.

  Note

  Activating user management

  The login to the Runtime project requires that its user management is active in Runtime.

  After starting a project manually, you have to activate its user management manually.

- If the "Reset logging data" option was enabled, the following data is deleted when Runtime is started:
  - Logging tags
  - Log alarms
  - Logged context values
- If the "Reset Runtime data" option was enabled, the following data originating from the last runtime of the project is deleted when Runtime is started:
  - The last values of internal, persistent tags
  - The last alarm states
  - The persistent attributes of the alarm system
  - The persistent attributes for the last logging cycle of the logging tags.

See also

Activating user management (Page 7508)

17.4.5 Adding a project

You have the option of loading projects from an external storage medium into Runtime with the Runtime Manager.

Requirement

- The external storage medium with the Runtime project is connected to the computer.
- The Runtime Manager is open.
- To download a project for which only the changes to the project have been downloaded to the external storage medium, the following additional requirements must be met:
  - The project that is to receive the changes is running on the HMI device.
  - The Runtime ID of the running project and the project on the external storage medium match.

Procedure

1. In the toolbar, click "Add project from offline transmission": 
   The "Add projects" dialog box opens.
2. Under "Select project log", click "...".
   A selection dialog opens.
3. Select the compressed ZIP folder of the Runtime project on the storage medium.
4. Click "Open".
   Under "Project information" you can see details of the selected project.

5. For a project that has been completely loaded onto the external storage medium, set the following options:
   - To start the project in Runtime after loading, select the "Start Runtime with project" option under "Options".
     Alternatively, you can start the project later in Runtime Manager.
   - Define whether project data is reset on startup.
     To start the project in a state that existed when the project was first started, activate the options "Reset logging data" or "Reset Runtime data".
     Disable these options to start the project in a state that existed before the last project stop.
     For more information on which data is reset with these options, see section Starting the project (Page 7495).
   - Under "Check IDs", determine whether or not to check the synchronization of IDs between engineering data and runtime data.
     Check activated: If inconsistent IDs are reported, the download is canceled. The IDs are then not synchronized.
     Check not activated: The project is loaded without checking. The system cannot guarantee that the data loaded from the Engineering System match the data present in Runtime.

   Note

   Restart Runtime

   To prevent data inconsistencies, restart Runtime when you select "Do not Sync".

6. To overwrite the Runtime UMC data with UMC data from the project, select the "Overwrite UMC data with the context of the offline loading" option under "Options".
7. Confirm with "Add project".

Result

- The project is downloaded to Runtime and appears in the project list.
- When "Start Runtime with project" is activated: The running project is stopped and the downloaded project is started. Depending on your settings, the Runtime data and log data of the project is reset and the Runtime UMC data is overwritten by the UMC data from the project.

Note

When you load a project from an external storage medium, the SIMATIC Runtime Manager extracts the repository to a temporary folder on the target system. The transfer to Runtime takes place from this folder, which is then deleted again.

17.4.6 Selecting an autostart project

Requirements

- At least one project is loaded into Runtime.
- The Runtime Manager is open.

Procedure

In the project list for the desired project, select the option in the "Autostart" column.

Note

Restrictions

- You can only select one project for autostart at a time.
- The project must not have the "Simulation" project type.

Result

The project is started automatically when the device on which the Runtime is installed is started.

17.4.7 Restoring and deleting log segments

In Runtime you have the option of restoring segments from logs for which a backup was created.

You can visualize the restored data in a trend control, for example.

Note

Database type for backups

Backups can only be created if the Microsoft SQL database type is used.

You can find more information on logs in the help of the TIA Portal.

Requirement

- At least one backup of a tag or alarm log is available.
- A project is loaded into Runtime and is in the "Running" state.
- The Runtime Manager is open.

Restoring log segments

1. Select the project.
2. Click "Restore/delete database segments for logs".
   A dialog opens.

3. Select the log type:
   - "Alarm" for alarm logs
   - "Tag" for data log
4. If required, select the relevant log in the selection menu.
5. If required, define a start time or end time.
   If you define a start time, all entries from this point in time are restored.
   If you define an end time, all entries up to this point in time are restored.
   If you define a start time and an end time, all entries between the defined points in time are restored.
6. If you have moved the backup of the log to be restored, enter the changed storage path of the backup under "Backup path".

   Note

   Only one log can be restored using the "Backup path" option.

7. Click "Restore segments".
   The selected segments are restored.
   If you have selected a time period, data may be restored beyond the selected period, as the restoration is carried out segment by segment.
   Information on the restoration can be found under "Status".

Delete log segments

To delete all previously restored segments of the tag logs or alarm logs, follow these steps:

1. Select the log type:
   - "Alarm" for alarm logs
   - "Tag" for data log
2. Click "Delete segments".

   Note

   All restored segments of the selected log type are deleted regardless of the log or the defined period.

   Information on the deletion process can be found under "Status".

17.4.8 Enter password

For secure communication with Runtime, the same password must be stored in the Runtime Manager as in Runtime.

Requirement

The Runtime uses secure communication.

Note

Enabling secure communication

Secure communication for Runtime can be enabled as follows:

- During the installation of the Runtime, in the step "Secure Download";
  Or after the installation in the application "WinCC Unified Configuration".
- In the Engineering System, if encrypted transmission is configured in the Runtime settings of a device and the option "Allow initial password transfer via unencrypted download" is enabled when downloading the device to Runtime.
  After the first, unencrypted transmission, the Runtime switches to secure communication.

Enter password for secure communication

1. Click the button in the toolbar.
2. Select the "General" tab.
3. Under "Secure connection", enter the same password that is used by Runtime for secure communication.
   For more information, refer to the "SIMATIC Unified PC Installation" user help under "Secure download".

Note

If Runtime does not use secure communication, the password entered here is ignored during communication with Runtime.

17.4.9 Setting general settings

Enable Autoscale

Proceed as follows to automatically adapt the size of HMI screens to the window size of the browser in which a Runtime project is open:

1. Click the button in the toolbar.
2. Select the "General" tab.
3. Under "Autoscale", select the "Adapt screen to window" check box.
4. Restart the currently running project or start another project that is loaded into the Runtime.

When users zoom in or out of the browser window, the HMI screens automatically adapt. Users always see the entire screen.

Changing the user interface language

Proceed as follows:

1. Click the button in the toolbar.
2. Select the "General" tab.
3. Select a language under "Language > Select language".
4. Click "OK".
   Changing the interface language requires you to restart the Runtime Manager. To restart the Runtime Manager directly, confirm the message that opens with "OK".

17.4.10 Activating automatic login

Introduction

Automatic login to Runtime can be enabled for local web clients of a Unified PC.

A local web client is a web client located on the same HMI device as Unified Runtime.

Requirement

- The HMI device is a Unified PC.

Procedure

1. On the HMI device, open the SIMATIC Runtime Manager as administrator.
2. Click the button in the toolbar.
3. Select the "General" tab.
4. Under "Automatic login", activate the "Enable automatic login" option.
5. Enter the user name and password of the UMC user that automatic login is to use if no UMC user is logged into Runtime via UMC Desktop Single Sign-on yet when the local web client is started or on login to Runtime.
6. Confirm your entries with "OK".
7. Restart Runtime.

Result

- On the start of a local web client or on connection to Runtime, the web client automatically authenticates itself with the following user data:

A UMC user is already logged in on the HMI device via UMC Desktop Single Sign-on (DSSO)	
Yes	The logged-in user is used.
No	The user configured in SIMATIC Runtime Manager is used. If no user has been configured in SIMATIC Runtime Manager, a hard-coded default user without function rights is used.

  All local web clients use the same logged-in user.
- Operators see the start screen of the project running in Runtime.
- If the logged-in user does not have the authorization to operate a screen element, a login dialog opens.
  To operate the screen element, the operator must log in with a user with corresponding function rights. The open process screens remain open.
- After logout of the user used for automatic login, for example, via the "LogOff" system function, or after switchover to another user, automatic login is only possible again after Runtime is restarted.
  Logout takes effect in all applications that use DSSO. The local web client switches to the hard-coded default user without function rights. The open process screens remain open.

17.4.11 Allowing start of external processes

Introduction

System functions that start an external process in runtime can be configured in the engineering.

Example: The `OpenTIAPortalProject` system function, which starts the TIA Portal, can be called in runtime in the process diagnostics.

Procedure

To allow runtime to start an external process when such a system function is called, follow these steps:

1. On the HMI device, open the SIMATIC Runtime Manager.
2. Click the  button in the toolbar.
3. Select the "Security" tab.
4. Enable the "Allow start of external processes via Unified Runtime" option.

17.4.12 Managing certificates

External communication partners are devices that exchange data with WinCC Unified Runtime via a secured connection. These devices use certificates for authentication that are either self-signed or issued by another certificate authority.

Examples: An S7PLUS device or an external OPC UA communication partner

Introduction

The "Certificates" tab provides you with the following options:

- Manage the trusted certificates of the external communication partners of the Unified HMI device (certificates, root certificates, and CRL files).
- Export the certificates of the external communication partners to distribute them to other Unified HMI devices (certificates, root certificates, and CRL files).
- Export the root certificate of the Unified HMI device and its CRL file (= Certificate Revocation List) to distribute it to external communication partners.

  Note

  Alternative method

  Export the root certificate and the CRL file of the Unified HMI device using the "WinCC Unified Certificate Manager". You can find additional information here (Page 7543).

- Import the root certificate of the Unified HMI device and its CRL file separately from the remaining certificate configuration.
  The root certificate is installed by the import.

  Note

  Alternative method

  Install the root certificate and the CRL file of the Unified HMI device together with the remaining certificates configured for the device using the "WinCC Unified Certificate Manager". You can find additional information here.

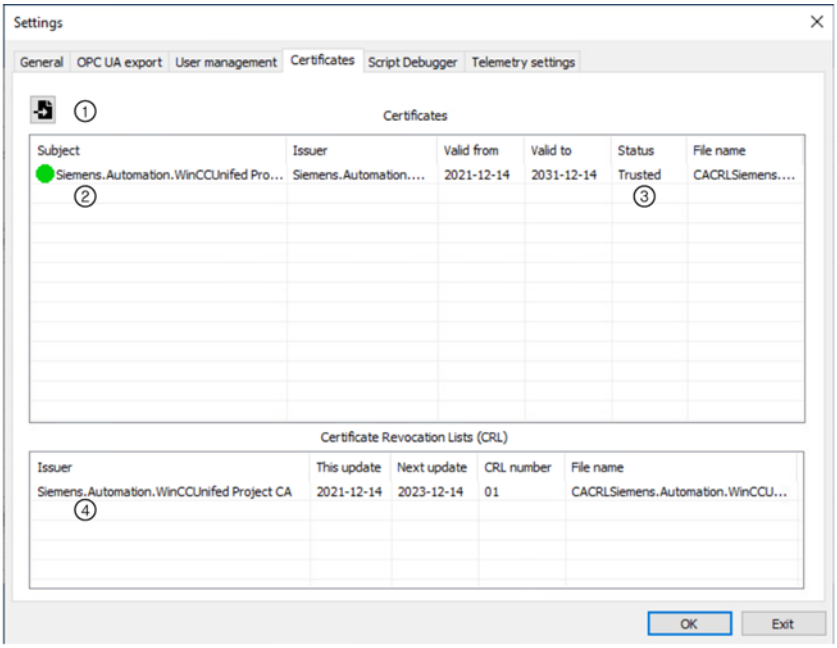
Note

Importing and exporting CRL files

The root certificate of the Unified HMI device and its CRL file must be imported separately.

When you export the root certificate of a CRL file, the CRL file is also exported. If required, you can export the CRL file separately.

Structure



① Button for importing a certificate or CRL file

By importing a certificate, you trust the certificate. You can later reject the certificate and trust it again.

② List of certificates

The following certificates are displayed:

- The root certificate installed on the Unified HMI device.
- The imported third-party certificates:
  - Application certificates (self-signed or issued by a certification authority).
  - Root certificates issued by the issuing certification authority.

③ Shows whether the HMI device trusts a certificate.

④ List of CRL files

Requirement

- The Runtime Manager is open.
- The certificates and CRL files to be imported are located in a folder to which the HMI device has access.

Managing certificates

1. Click the button in the toolbar.
2. Select the "Certificates" tab.
3. You can perform the following actions:

Action	Procedure
Import and trust	1. Click "Import new certificate or certificate revocation list (CRL)": 2. Select the location where the certificate is stored, for example, an external data carrier, and select the certificate. 3. Confirm your input. The certificate is imported and copied to the "trusted" folder on the HMI device.
Trust	Right-click on a certificate and select "Trust". The certificate is moved to the "trusted" folder on the HMI device.
Reject	Right-click the certificate and select "Reject". The certificate is moved to the "untrusted" folder on the HMI device.
Display	Right-click on a certificate and select "Show". A window with detailed information on the certificate opens.
Delete	Right-click on a certificate and select "Delete". The certificate is deleted from the certificate store on the HMI device.
Export	1. Right-click the certificate and select "Export". 2. If you have selected a root certificate, select the file format. 3. Select the target folder, for example, an external data storage medium. 4. Confirm your input. The certificate is copied to the target folder. If you have selected a root certificate, its CRL file is also copied. Distribute the files to the desired devices. To do this, proceed as described in the application help of the device.

Managing CRL files

1. Click the button in the toolbar.
2. Select the "Certificates" tab.
3. You can perform the following actions:

Action	Procedure
Import	1. Click "Import new certificate or certificate revocation list (CRL)":  2. Select the location of the CRL file, e.g. an external data storage medium, and select the file. 3. Confirm your input. The file is imported and copied to the "trusted" folder on the HMI device.
Delete	Right-click on a CRL file and select "Delete". The file is deleted from the "trusted" folder on the HMI device.
Export	1. Right-click on the CRL file and select "Export". 2. Select the file format. 3. Select the target folder, for example, an external data storage medium. 4. Confirm your input. The CRL file is copied to the target folder. Distribute the files to the desired devices. To do this, proceed as described in the application help of the device.

Introduction to the WinCC Unified Certificate Manager (Page 7517)

17.4.13 Exporting tags via the OPC UA server

In the "OPC UA Export" tab, you can export the tags of the project running in Runtime via the OPC UA server into an XML file. The exported data can then be imported into another application, e.g. the TIA Portal, without the need for a connection to the OPC UA server.

The export makes it easier for you to apply an existing configuration to a new Runtime system.

You can find a detailed description in the help "OPC UA - Open Platform Communications". To do this, open the following file after installing Runtime: "<Path to the Unified installation directory>\Documentation\<Language folder>\OPCWCCU<Language code>.pdf"

For example C:\Program Files\Siemens\Automation\WinCCUnified\Documentation\English\OPCWCCUenUS.pdf

17.4.14 Activating user management

Introduction

Several projects can be loaded on one Unified PC. The configuration of their user management may differ. For a successful login to a project in Runtime, the project must be running in Runtime and the appropriate user management must be active.

In the "User administration" tab, activate the appropriate user administration. For a project with central user management, you can also adapt the connection settings to the UMC server, e.g. to add missing settings in the TIA Portal or to use different settings.

Configuring the user administration

The user management of a project is configured in the TIA Portal under "Runtime settings > User management". In the Runtime Manager, it is not possible to switch a project from local to central user management.

You can find information on configuring the user management in the TIA Portal in the TIA Portal online help.

You can find information on how to configure the runtime system settings for user management during runtime installation or later with WinCC Unified Configuration here.

Requirement

- In the Runtime system settings, it has been specified that Runtime uses the user management configuration downloaded from the TIA Portal.
- At least one user has been configured with an HMI function right for the user management active in Runtime.
- At least one user has been configured with an HMI function right for the user management that you want to activate.
- The Runtime Manager is open.
- A project is running in Runtime, and:
  - The active user management does not match the user management configured for the project.
  - For projects with central user management: The connection settings configured in the TIA Portal for the project are incomplete, or you want to use different settings.

Procedure

1. Click the button  in the toolbar.
2. Select the "User management" tab.
3. Under "Select configuration", in the "From" list, select the project whose user management configuration you want to activate in Runtime.
   Default setting after starting the Runtime Manager: The project running in Runtime

4. Confirm the confirmation prompt.
   The "Operating mode" area shows the operating mode of the user management of the selected project. The displayed options are read-only.
5. If the project selected under "From" uses local user management, click "Load user management".
   User management is activated in Runtime:
   - The user data pre-configured in the TIA Portal for the project is loaded into the local user management.
   - Runtime uses the local user management.
   - The "Status" field shows the status of the user management.

NOTICE
Possible data loss The user data configured in the TIA Portal overwrites the user data added or changed on the HMI device in the local user management. Data loss can occur.

6. If the project selected under "From" uses central user management, proceed as follows:
   - Add missing or incorrect information about the connection settings.
     By default, the identity provider address is automatically generated based on the UMC server address.
     To enter the address of the identity provider manually, deactivate the option "Generate the address of the identity provider automatically".
     To set all fields to empty, click "Reset configuration".
   - Click "Connect to server".
     The system will notify you if the configured server ID and the server ID reported during the connection attempt are different from each other. To continue with the ID reported online, click "Yes"; to continue with the configured server ID, click "No".

   User management is activated in Runtime:
   - A connection to the UMC server is established using the connection settings from the Runtime Manager.
   - Runtime uses the UMC server for user management.
   - If you later select the project under "From", the connection settings you entered are loaded.

17.4.15 Setting the Runtime Script Debugger settings

The scripts of the screens and jobs of a Runtime project can be tested using the Google Chrome script debugger.

To this end, the debugger must be configured and enabled in advance in the "Script debugger" tab in the Runtime Manager.

Enabling the debugger (Page 7483)

17.4.16 Enabling telemetry service

Introduction

The telemetry service is used to analyze problems occurring in Runtime projects. It helps the Siemens support team to support you in analyzing and correcting such problems in the best possible way. The service generates an encrypted ECD file that combines the visual recording of the process running in runtime with the recording of detailed internal system information about the process.

The ECD file records the following information from the project running in runtime:

- Screen configuration of the visible screens
- User input with mouse and keyboard
- IO addresses of all connections
- Property values of the underlying CHROM objects

Note

- Enable the telemetry service only after being requested by the Siemens support team.
- The size of the ECD file depends on the length of the recording, the number of connections and the events in the process.
- The ECD file contains machine-specific and user-specific data such as user names, but not passwords.
  This data is visible to the Siemens support team. The data is not processed or stored longer than necessary.

Requirement

SIMATIC Runtime Manager has been started in admin mode.

Enabling telemetry service

1. Click the  button in the toolbar.
2. Select the "Telemetry settings" tab.
3. Under "Storage directory", specify the path to the directory where the ECD file is to be stored. Use an already existing directory.
4. Enable the "Enable telemetry" option.
5. Restart Runtime.

The telemetry service will be enabled for the currently running project.

Next steps

1. Reproduce the error scenario in Runtime.
2. Stop the telemetry service by disabling the "Enable telemetry" option and restarting Runtime.
3. Submit the ECD file to the Siemens Support team.

17.4.17 Operation via command line

The Runtime Manager has an interface with which you can start numerous functions of the Runtime Manager via a command line program:

Requirement

- Runtime and command line program are installed on the same device.
- For starting/stopping projects: Projects have been loaded into Runtime.

Procedure

1. Start the command line program.
2. Enter the command line call. Separate the individual elements of the call with spaces.
   - Enter the path to the SIMATIC Runtime Manager.exe:
     "<Runtime installation directory>\bin> start /wait SIMATICRuntimeManager.exe"
     Example: C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait SIMATICRuntimeManager.exe
   - Enter the options with which the command line program calls the Runtime Manager. The last option must be "-c".

Option	Description
`-s`	Option for starting the Runtime Manager in silent mode. Without this option, the UI of the Runtime Manager is started when the command line call is processed.
`-u`	Option to enable help messages that assist you in operating the Runtime Manager via the command line program.
`-sim`	Only use this option if you call the option "-c" with the command `projectstate`, `start`, `stop` or `remove`.
`-quiet`	Option for calling the Runtime Manager without output.
`-o`	Option for diverting the output into an Output.txt file that is stored parallel to SIMATICRuntimeManager.exe. You can redirect the output to another folder. The Unified Administrator must have write access to the folder. Example: `-o "C:\Program Files\Siemens\Automation\WinCCUnified\bin\MyOutput.txt"` If an error occurs during the write and -quiet is not set, the error indication appears on the console.
`-keepUmc`	Optional Only in combination with the `fulldownload` command Set the option to keep the Runtime UMC data.
`-overwriteUmc`	Optional Only in combination with the `fulldownload` command Set this option to replace the UMC data of the Runtime with the UMC data from the project.
`-c`	Option for inputting the commands that are transmitted to the Runtime Manager.

– After the option "-c", enter the command that the Runtime Manager should run and the argument that is transmitted to the command:

Command	Argument	Description
`start`	<Project ID>	Starts the project.
`stop`	<Project ID>	Stops the project.
`projectlist`	[ALL] or [RUNNING] Default: [ALL]	`[ALL]`: Returns a list of projects loaded in the Runtime. `[RUNNING]`: Returns the project running in Runtime.
`projectstate`	<Project ID>	Returns the state of the project running in Runtime.
`remove`	<Project ID>	Removes the project from Runtime. If the autostart option was previously set for the project: Removes the autostart option.
`securemode`	<Password>	Sets the password for secure communication with SCS. Enter the same password that Runtime uses for secure communication.
`setautostart`	<Project ID>	The project is started when the device is booted. The project must have the Project type. The option can only be set for 1 project.
`removeautostart`	<Project ID>	Removes the autostart of the project.
`fulldownload`	<Log path>	Starts the full download of a TIA Portal log. If the project is already running in Runtime, it is stopped first before the full download. To start the project after successful download, use the command `start`.
`deltadownload`	<Log path>	Starts the change loading of a TIA Portal log. Check in advance if the corresponding project is downloaded and running in Runtime.

To run multiple commands, use multiple command line calls.

3. Press Enter.

Result

- The command is executed.
- A return code with description is output in the console.
  List of possible return codes:

Return code	Description
0x00000000	Success
0x0080400b	Project already running
0x0080400c	Project started
0x0080400d	Project already stopped
0x0080400e	Project stopped
0x80000000	General error
0x80000001	Not supported (e. g. wrong command)
0x80000003	Timeout during communication with SCS
0x80000004	Invalid arguments
0x80000005	Access denied – password required for secure connection
0x8000000C	Another project is currently flagged as autostart project, remove autostart from the other project
0x80000016	Unable to connect to SCS
0x80804019	Project not found
0x80B0412E	Write output file error
0x80B0412F	Autostart option cannot be set on simulation project
0x80B04130	Empty command value
0x80B04131	archive target path could not be created
0x80B04132	project archive can not be extracted
0x80B04133	DownloadTask file can not be read
0x80B04134	Could not change UMC Data override option
0x80B04135	Missing config folder in archive
0x80B04136	Missing delta folder in archive

- An output is written to the console or to the output file.
  Requirement: The command was called without the -quiet option.

Examples

- Call a list of all projects loaded into Runtime:
  - Input: `C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait SIMATICRuntimeManager.exe -s -c projectlist [ALL]`
  - Example output:

```
[1]
 Project name:  T1
 Device name:  T1
 Project type:  Project
 Project ID:  0B527D12-6BBD-4F2F-BEB9-23E3C37A8932
 Autostart:  0
[2]
 Project name:  T2
 Device name:  T2
 Project type:  Project
 Project ID:  29DCBA1D-C615-4560-AFB4-94EB9565682C
 Autostart:  0
[3]
 Project name:  T3
 Device name:  T3
 Project type:  Project
 Project ID:  96FE68D0-5337-4072-A96C-F7C1D7525CAF
 Autostart:  0
```

- Call the project running in Runtime:
  Input:
  `C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait SIMATiCRuntimeManager.exe -s -c projectlist RUNNING`
- Query project state:
  Input:
  `C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait SIMATICRuntimeManager.exe -s -c projectstate 96FE68D0-5337-4072-A96C-F7C1D7525CAF`
- Start a project:
  Input:
  `C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait SIMATICRuntimeManager.exe -s -c start 96FE68D0-5337-4072-A96C-F7C1D7525CAF`
- Stop a project:
  Input:
  `C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait SIMATICRuntimeManager.exe -s -c stop 96FE68D0-5337-4072-A96C-F7C1D7525CAF`
- Remove a project from Runtime:
  Input:
  `C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait SIMATICRuntimeManager.exe -s -c remove 96FE68D0-5337-4072-A96C-F7C1D7525CAF`

- Example of a query regarding the state of a simulation project:
  Input:
  ```
  C:\Program
  Files\Siemens\Automation\WinCCUnified\bin>SIMATICRuntimeManager.ex
  e -s -sim -c projectstate 96FE68D0-5337-4072-A96C-F7C1D7525CAF
  ```
- Set password for secure communication with Runtime:
  Input:
  ```
  C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait
  SIMATICRuntimeManager.exe -s -c securemode <password>
  ```
- Enable autostart for a project:
  Input:
  ```
  C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait
  SIMATICRuntimeManager.exe -s -c setautostart 28AC5BD5-0741-42D1-
  B3C6-503359F32B7E
  ```
- Disable autostart for a project:
  ```
  C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait
  SIMATICRuntimeManager.exe -s -c removeautostart
  28AC5BD5-0741-42D1-B3C6-503359F32B7E
  ```
- Perform a full download of a TIA Portal log:
  Input:
  ```
  C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait
  SIMATICRuntimeManager.exe -s -c fulldownload
  "C:\Users\admin\Desktop\ HMI_RT_1[Project1] - Full 2019-10-21 -
  08.00.22.zip"
  ```
- Download only the changes of a TIA Portal log (delta download):
  Input:
  ```
  C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait
  SIMATICRuntimeManager.exe -s -keepUmc -c fulldownload
  "C:\Users\admin\Desktop\HMI_RT_1[Project1] - Full 2020-03-27 -
  11.39.51.zip"
  ```
- Retain UMC data during full download:
  Input:
  ```
  C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait
  SIMATICRuntimeManager.exe -s -c deltadownload
  "C:\Users\admin\Desktop\ HMI_RT_1[Project1] - Delta 2019-10-21 -
  08.03.18.zip"
  ```
- Replace UMC data during full download:
  Input:
  ```
  C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait
  SIMATICRuntimeManager.exe -s -overwriteUmc -c fulldownload
  "C:\Users\admin\Desktop\HMI_RT_1[Project1] - Full 2020-03-27 -
  11.39.51.zip"
  ```
- Enable help messages:
  Input:
  ```
  C:\Program Files\Siemens\Automation\WinCCUnified\bin> start /wait
  SIMATICRuntimeManager.exe -s – u
  ```

17.5 Certificate Manager

17.5.1 Basics

17.5.1.1 Introduction to the WinCC Unified Certificate Manager

Protection through certificates

Communication within the plant must be protected to secure plants, systems and networks against cyber threats. Security-relevant components of WinCC Unified devices therefore use encrypted communication protocols.

It is recommended to use certificates created with a certificate authority for this communication. In this case, each communication partner is assigned a unique certificate that is used for authentication and encryption.

Task of the WinCC Unified Certificate Manager

With WinCC Unified Certificate Manager you create a certificate authority. Then, with the certificate authority, create the certificates of the Unified devices and distribute them.

On Unified PCs, you also install the certificates via Certificate Manager. On Unified Comfort Panels, use the Control Panel to do this.

Note

No support for certificates from external certification authorities

The use of the Certificate Manager is required to issue certificates for Unified Runtime via a certificate authority.

Functions

The Certificate Manager offers you the following functions for the creation, distribution and installation of the certificates:

- Central creation of certificates for Unified devices in the network
- Creation of a certificate authority

- Creation of the application certificates for the following WinCC Unified components:
  - WinCC Unified Runtime (Webserver (IIS))
  - WinCC Unified OPC UA server
  - WinCC Unified OPC UA exporter
  - WinCC Unified OPC UA client
  - WinCC Unified Runtime Collaboration
  - WinCC Unified Audit Trail system
- Renewing existing certificates
- Encrypted export of the certificates for manual distribution to the Unified devices
- Encrypted import and installation of certificates on Unified PCs
- Encrypted export and import of the root certificate, CRL file, and private key, as well as all device certificates for data backup and recovery.
- Export of the root certificate and its CRL file for distribution to external communication partners
- Export an updated CRL file for distribution to Unified devices and external communication partners.

Additional information

You can find more information about the deployment of certificates under "How to use certificates" in the user help "SIMATIC Unified PC Installation".

17.5.1.2 Certificate authority

Total configuration of the certificate authority

The total configuration of the certificate authority (CA) includes:

- The private key
  The certificate authority uses it to sign the application certificates. The private key remains on the certificate authority device.
- The public key/root certificate (CA certificate) and a CRL file (Certificate Revocation List).
  Root certificate and CRL file are distributed to the Unified devices and their external communication partners.

  Note

  This help uses the runtime root certificate.

- The devices added to the certificate authority and their application certificates.

CA container

The CA container (Certificate Authority container) includes:

- The root certificate
- The CRL file
- The application certificates of all devices added to the certificate authority

17.5.1.3 Required certificates

Introduction

You need the following certificates to use a Unified device:

- Root certificate of the certificate authority and its Certificate Revocation List (CRL file)
- The application certificates issued by the certificate authority

These certificates form the certificate configuration of the Unified device.

Root certificate and CRL file

The root certificate of the certificate authority and its CRL file must be distributed to the Unified devices and the external communication partners.

The trust relationship between a Unified device and its communication partners is established by the devices trusting each other's root certificates.

Unified devices whose certificates come from the same certificate authority automatically trust each other after installing their certificate configuration.

Application certificates

The device requires the following application certificates:

- For accessing WinCC Unified Runtime via a web page:
  The device with the Unified Runtime installation requires a web server certificate.

  Note

  A web server (IIS) must also be installed on the device.

  The web clients can access the runtime web page only if the root certificate of the web server certificate on the clients has been previously configured once as trusted in the browser.
  See Installing root certificate for access via web client (Unified PC) (Page 7545).

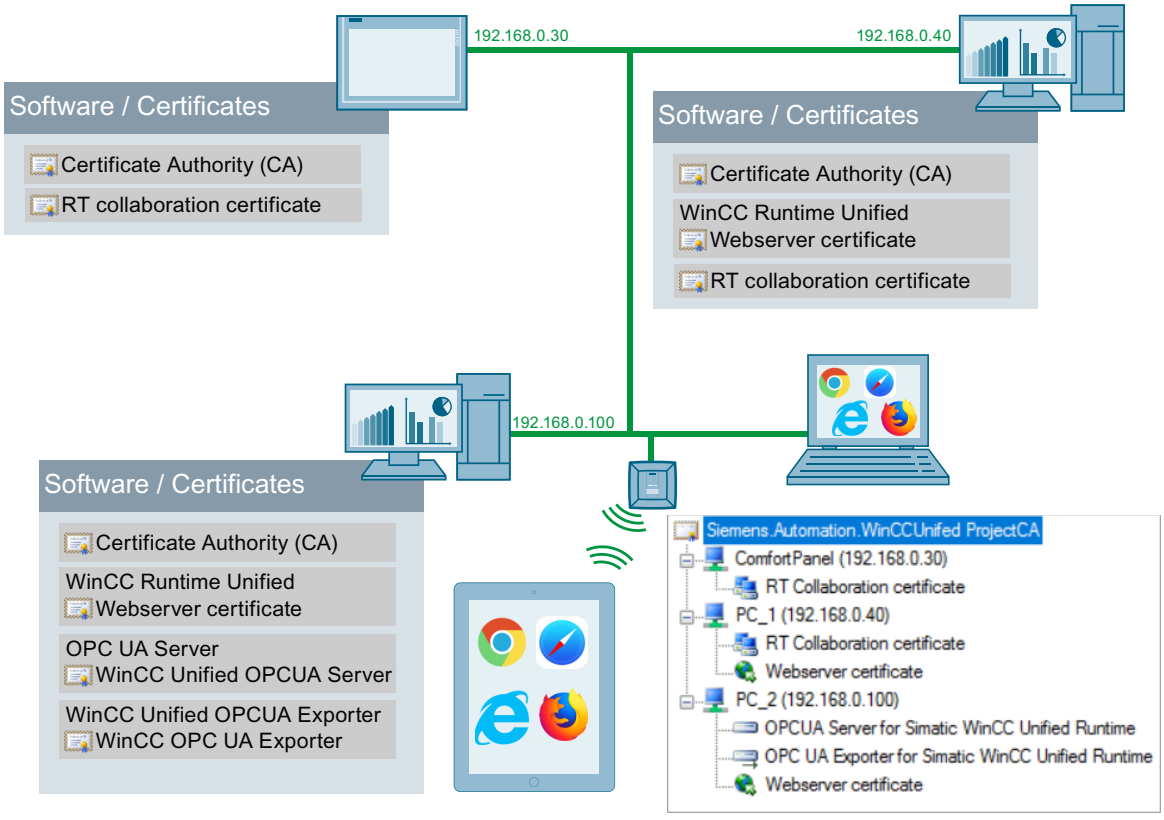
- For data exchange between Unified devices (WinCC Unified Collaboration):
  The devices require a Runtime Collaboration certificate.

- For OPC UA communication between devices:
  - A Unified device used as OPC UA server requires an OPC UA Server certificate and an OPC UA Exporter certificate.
    Alternatively, you can use the self-signed default certificates generated for the OPC UA server and OPC UA exporter.
  - A Unified device that is to communicate with an OPC UA server requires an OPC UA client certificate.
- For GMP-compliant use of a unified device:
  The device requires an Audit Trail System certificate.

Example

Two Unified PCs and one Unified Comfort Panel are operated in the following example:

- The PCs provide web pages for runtime visualization. Therefore, you need a web server certificate.
- A PC (192.168.0.100) runs an OPC UA server. Therefore it requires the Unified OPC UA Server and OPC UA Exporter certificates.
- The panel (192.168.0.30) and a PC (192.168.0.40) should exchange runtime data. Both devices require a Runtime Collaboration certificate.
- The root certificate is installed and classified as trustworthy on all devices.
- When accessing the Runtime web pages from external devices via a browser, the root certificate must be installed in the browser's certificate store. The Unified Runtime start page provides a corresponding download link.



See also

Exporting root certificate and CRL file (Page 7543)

17.5.1.4 Password requirements

The passwords defined in the Certificate Manager must meet the following requirements:

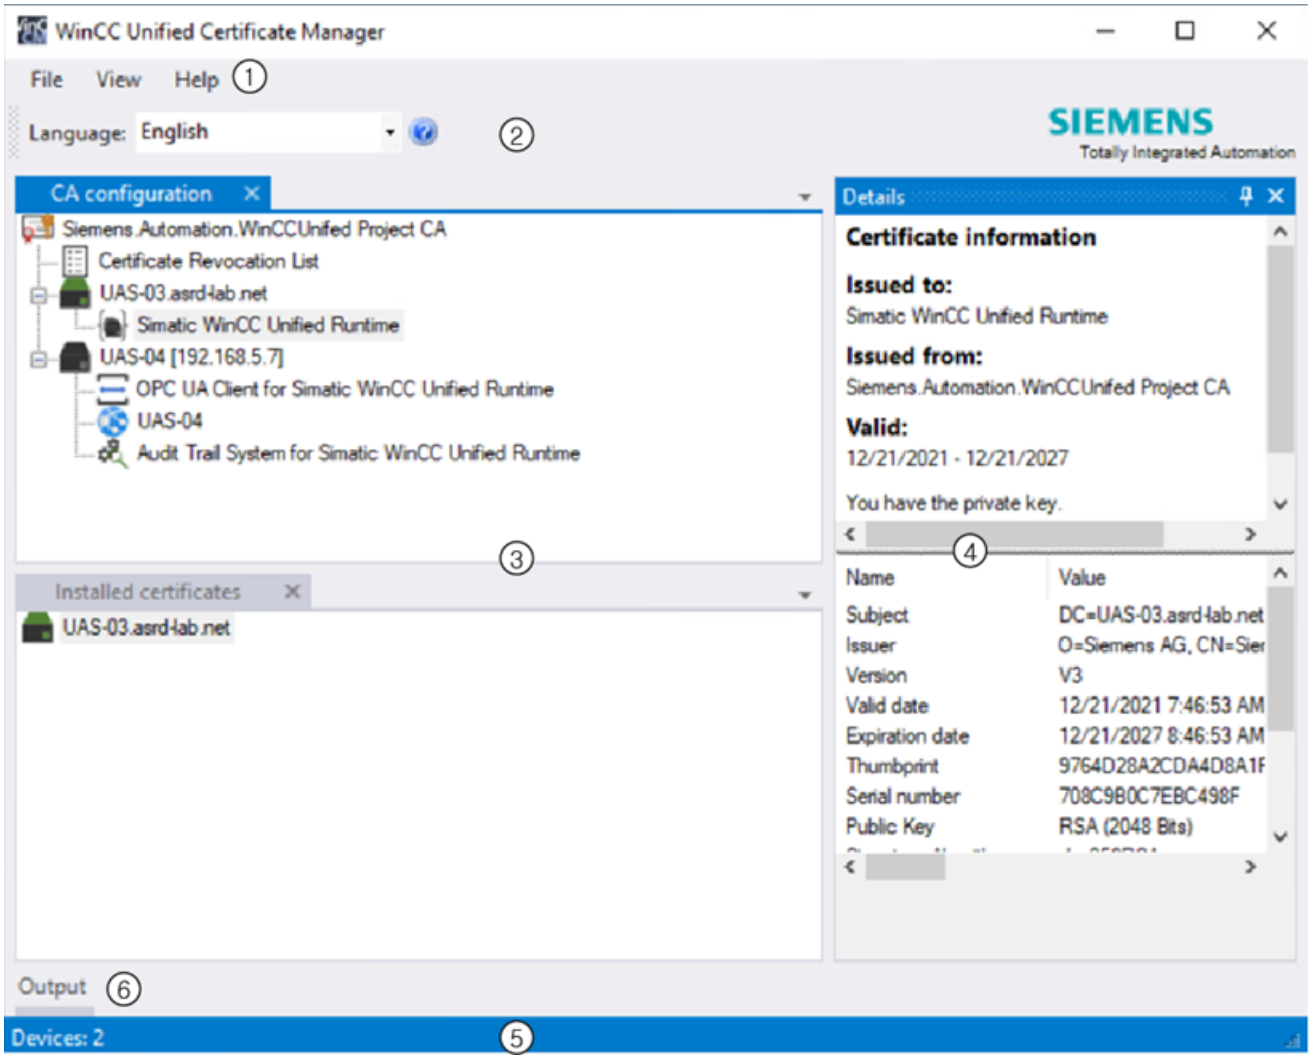
- Length: At least 8 characters
- In each case at least one uppercase letter, one lowercase letter, one number and one special character

17.5.2 Certificate Manager interface

17.5.2.1 Structure of the user interface

Overview

The interface of WinCC Unified Certificate Manager has the following structure:



① Menu bar

② Toolbar

③ Work area with the "CA configuration" and "Installed certificates" tabs

④ "Details" area (fixed)

The "Details" area shows you detailed information about the certificate selected in the work area.

⑤ Information bar
⑥ "Output" area (hidden)
The "Output" area logs operator control actions.

You can customize the display of the interface to suit your needs. See also Customize surface (Page 7525).

Menu bar

Menu	Description
"File > Exit"	Closes Certificate Manager.
"View"	Configure which Certificate Manager interface elements you see. You can open or close the following interface elements: • "Output" area • "Details" area • "CA configuration" tab • "Installed certificates" tab
"Help"	"Certificate Manager Help" Opens the user help in a browser.
	"Info Certificate Manager" Opens a dialog with information about the installed software version.

Toolbar

Button	
	To change the user interface language
	To call the user help

Tab of the working area

See "CA configuration" tab (Page 7523) and "Installed certificates" tab (Page 7525).

17.5.2.2 "CA configuration" tab

On a certificate authority device

On a certificate authority device, you create and configure the certificate authority in the "CA configuration" tab:

- You create the certificate authority and its root certificate.
- You add devices.
- You create the application certificates of the devices.

- You carry out exports:
  - To make the certificates available on other devices
  - To backup data
- You recreate certificates.
  You have the following options:
  - Recreating a root certificate
  - Updating a CRL file
  - Recreating a certificate configuration of a device
  - Recreating a single application certificate of a device
- When the certificate authority device is used as a Unified PC: You install the application certificates of the device.

Note

Content of the tab

After starting Certificate Manager, you will see the same data that the certificate authority had when you last closed Certificate Manager:

- If no data has been generated yet, you will see the nodes "Open configuration ..." and "Create certificate authority ..."
- If data has already been generated, you will see the root certificate and its CRL file, as well as the configured Unified devices and their application certificates.
  You can edit them.

On standard Unified PCs

On Unified PCs that do not serve as a certificate authority, you perform the following actions in the tab:

- You import the certificate configuration of the device
- You install the entire certificate configuration or a single application certificate
- You delete installed certificates

Note

Content of the tab

After launching Certificate Manager, you will see the nodes "Open new configuration ..." and "Create certificate authority ..."

After opening a new configuration, you will see the root certificate of the certificate authority and its CRL file, as well as the Unified devices configured at the certificate authority and their application certificates.

You can install only the certificate configuration of the local device. The display of the certificate configuration of the other devices is for information purposes. You cannot change their certificate configuration.

Closing Certificate Manager also closes the configuration.

See also

Structure of the user interface (Page 7522)

17.5.2.3 "Installed certificates" tab

In the "Installed certificates" tab, you can see which application certificates are installed on the local device.

You have the option to uninstall certificates by deleting them.

See also

Structure of the user interface (Page 7522)

17.5.2.4 Customize surface

Display and arrangement of the interface elements of WinCC Unified Certificate Manager are configurable:

User interface elements	Close / Open	Move	Undock / dock	Fix / Unfix	Show / Hide
"Details" area	✓	✓	✓	✓	✓
"Output" area	✓	✓	✓	✓	✓
Tab of the working area	✓	✓	-	-	-

Closing and opening

To close a user interface element, click the "X" button. Alternatively, disable it in the "View" menu.

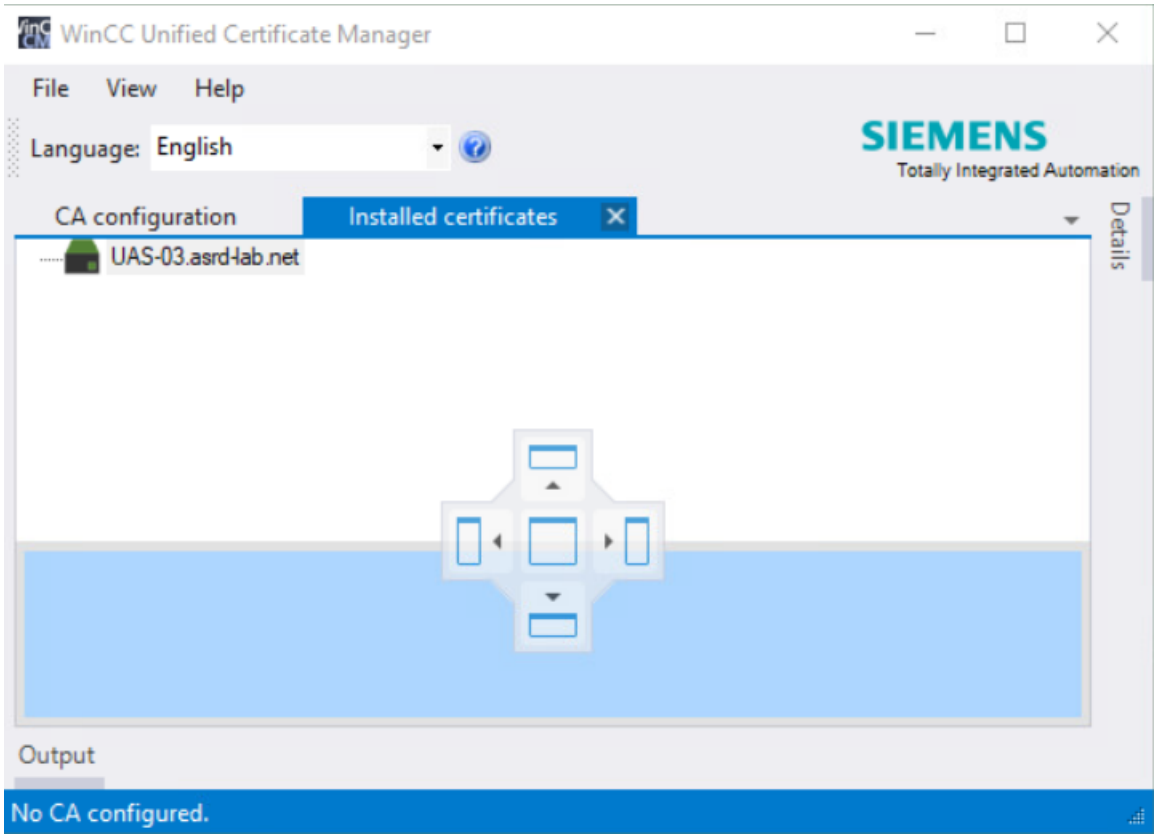
To open a closed user interface element, enable it in the "View" menu.

Move

1. Move the title bar of the desired user interface element with the left mouse button pressed. Possible insertion positions are displayed in the interface:

   The offered insertion positions depend on which element you move and which elements the application window already displays.

2. To see a preview of the new arrangement, move the mouse cursor to one of the positions and keep the mouse cursor pressed:



3. Release the mouse cursor over the desired insertion position.

The user interface element is moved.

Undocking and docking

When you move the header of the "Details" or "Output" area, the area is undocked from the application window and displayed as a standalone window. You can move the window freely.

To dock the area back to the application window, move it to one of the suggested insertion positions.

Fixing and unfixing

The following button fixes or unfixes the "Details" and "Output" areas:

Representation of the user interface	Status	Changing setting
	Fixed The area is displayed even if it does not have the focus.	Click the button to switch the setting.
	The area is hidden as soon as it loses focus.	

Showing and hiding

Requirement

The "Details" and "Output" areas are not fixed.

Procedure

To show an area, click on its text. The area is displayed.

It is automatically hidden when you click the mouse cursor outside the area.

17.5.2.5 Changing the user interface language

Procedure

1. Click the button with the arrow in the toolbar:

2. Select the desired language.

Result

Changing the user interface language

17.5.3 Making certificates available

This section describes which steps are required to provide certificates with WinCC Unified Certificate Manager.

Generating a certificate configuration

On the device that serves as the certificate authority, do the following.

1. Create the certificate authority.
   This creates the root certificate, CRL file and private key.
   See Creating a certificate authority and root certificate (Page 7530).
2. Add the required Unified devices to the certificate authority.
   See Adding devices (Page 7531).
3. Create the desired application certificates for the devices.
   See Add application certificates (Page 7533).

Exporting the certificate configuration

After you complete the certificate configuration of the devices, export the certificate configuration.

The procedures differ for PC devices and panel devices. See Exporting certificate configuration (Unified PC) (Page 7536) and Exporting the certificate configuration (UCP) (Page 7540).

Note

Distribution of the root certificate and CRL file

Root certificate and CRL file are part of the certificate configuration of a device. They are exported or imported with the certificate configuration, installed and classified as trusted.

Certificate Manager also offers the option of exporting the root certificate and CRL file individually, e.g. to distribute them to external communication partners.

On Unified PCs, you can also export the root certificate and CRL file via SIMATIC Runtime Manager. You can find additional information here (Page 7504).

For an overview of all Certificate Manager export options, see Export options (Page 7535).

Making certificates available on the Unified devices

To make the certificates of a Unified HMI device available on the device, follow these steps:

1. Import the certificate configuration.
   See Importing certificate configuration (Unified PC) (Page 7538) and Importing and installing certificate configuration (UCP) (Page 7541).
2. Install the entire certificate configuration or individual certificates.
   See Installing certificates (Unified PC) (Page 7539) and Importing and installing certificate configuration (UCP) (Page 7541).

The procedures differ for PC devices and panel devices.

Depending on the device, use the following tool:

- Unified Comfort Panel: Control panel > "Security" function
- Unified PC: WinCC Unified Certificate Manager

Trust communication partners

For successful communication, the Unified device must trust the root certificates of its communication partners and vice versa.

Trust relationship between Unified devices

Unified devices whose certificate configuration comes from the same certificate authority automatically trust each other after the certificate configuration is installed.

Relationship of trust with external communication partners

To establish the trust relationship with an external communication partner, follow these steps:

1. On the certificate authority device or on the Unified device:
   Export the root certificate and CRL file to an external data storage medium.
   See Exporting root certificate and CRL file (Page 7543).
2. On the external communication partners:
   - Connect the external communication partner to the external data storage medium.
   - Copy the files and trust them. To do this, proceed as described in the user help of the device.
   - Export the root certificate of the external communication partner and its CRL file to the external data storage medium.
3. Connect the external data storage medium to the Unified device.
4. Import the root certificate and CRL file of the external communication partner into the Unified device and trust it:
   - Unified PC: Use SIMATIC Runtime Manager.
   - Unified Comfort Panel: In the control panel of the device, under "Security", use the "Certificates" > "Import" function.

During the next connection attempt, the communication partners mutually accept their application certificates.

Recreating certificates

You have the option to recreate certificates.

See Recreating certificates (Page 7551).

See also

Importing and installing certificates manually (UCP) (Page 7542)

17.5.4 Creating a certificate authority and root certificate

Requirement

On the Unified PC that is to serve as a certificate authority, no certificate authority is created in WinCC Unified Certificate Manager.

Procedure

1. On your network, select the Unified PC that will be used as the certificate authority.
2. Open WinCC Unified Certificate Manager on this device.
3. Select the "CA configuration" tab.
4. In the work area, double-click "Create new certificate authority".
5. Enter the properties of the root certificate in the "New certificate authority" dialog. The fields are freely editable.
   Mandatory fields:
   - "Name"
   - Password fields for the private key
     See also Password requirements (Page 7521).

   If necessary, select a different cryptographic key length and runtime for the certificate.
6. Click "Create".

Result

- The private key is generated.
- The root certificate is generated.
- An empty CRL (Certificate Revocation List) file is generated.
- In the "CA configuration" tab, a node for the root certificate is created and below it one for the CRL file.

Note

The private key is only available on the certificate authority device. The certificate authority uses it to sign the application certificates of the Unified devices.

The root certificate and the CRL file are part of the certificate configuration of the Unified devices. They are exported or imported when the certificate configuration is exported or imported. During the installation of the certificate configuration on the device, they are automatically installed and classified as trusted.

Next steps

- Add the Unified devices to the root certificate and create their application certificates. See Adding devices (Page 7531) and Add application certificates (Page 7533).
- To distribute the Unified root certificate and its CRL file without the certificate configuration of the devices, for example, to external communication partners, export them individually. See Exporting root certificate and CRL file (Page 7543).

Deleting certificate authority and root certificate

NOTICE
Data loss prevention Delete the certificate authority and root certificate only in the following cases: • After you have saved the data of the certificate authority. • When you no longer need the certificate authority and its data.

Procedure

1. On the certificate authority device, open Certificate Manager.
2. Select the "CA configuration" tab.
3. Click the root certificate on the left and select "Delete".

Result

The certificate authority and all its data will be deleted from the device.

Note

If the certificate configurations were already installed on the Unified devices, the certificates are still installed there. Delete them there if necessary.

17.5.5 Adding devices

Requirement

A certificate authority has been created in WinCC Unified Certificate Manager on the Unified PC that is used as the certificate authority.

Procedure

1. On the certificate authority device, open Certificate Manager.
2. Select the "CA configuration" tab.
   You see the root certificate and its CRL file, as well as all the devices that have already been added and their application certificates.

3. Right-click the root certificate and select "Add device ...".
4. In the "New device" dialog, enter the device name, the IP address of the device, or both. When creating application certificates for this device, these entries are inserted into the certificates and used for the validation.

Note

Allowed device names

Either the host name or the fully qualified domain name can be used as the device name.

The use of the name "localhost" is not allowed and will be automatically replaced by Certificate Manager with the device name of the local device.

Note

Required inputs

- For devices in a domain, enter the fully-qualified domain name as the device name. This avoids validation errors when accessing the web pages.
- If the identity provider and Unified Runtime website are addressed by IP address, enter the IP address.
- For devices that are used as OPC UA servers, enter the device name.
- For devices with dynamic IP addresses, enter only the device name.

Result

A node for the device is generated in the "CA configuration" tab.

Icons of the device nodes:

The local machine (if added)

Other devices

Next step

Create the application certificates of the added device.

Delete device

Procedure

To delete a device, click on the device on the left and select "Delete".

Result

The device and its application certificates are deleted from the certificate authority.

Note

Deleting does not affect the certificate configuration installed on the device.

If necessary, delete the certificates from the device. On a Unified PC, you use Certificate Manager to do this. On a Unified Comfort Panel, use the "Security" function in the Control Panel.

Handling a device after changing the IP address or the computer name

If the IP address or the computer name of a device added in Certificate Manager is changed later, do the following:

1. Delete the device in Certificate Manager.
2. Create it again using the new IP or the new computer name.
3. Add the desired application certificates to the device.
4. Export the certificate configuration and distribute it.

See also

Creating a certificate authority and root certificate (Page 7530)

Add application certificates (Page 7533)

17.5.6 Add application certificates

Requirement

A device has been added to the certificate authority in WinCC Unified Certificate Manager.

Procedure

1. On the certificate authority device, open Certificate Manager.
2. Select the "CA configuration" tab.
3. Right-click on a device and select "Add <Certificate type> ..."

4. Enter the properties of the certificate in the "New certificate" dialog.
   If necessary, select a different cryptographic key length and runtime for the certificate.

   Note

   Runtime

   For web server certificates, the runtime is limited to a maximum of 27 months. Longer runtimes are not accepted by some browsers.

   Note

   Use the "Fully qualified domain name" as name for web server certificates.

5. Click "Create".
6. Repeat the last three steps until the device has the required application certificates.

Result

The certificate configuration of the device is completed.

Next step

Export the certificate configuration.

Note

If the certificate authority device is used as a Unified device, no export is necessary. You can install the certificate configuration or individual certificates directly.

Deleting an application certificate

Procedure

1. On the certificate authority device, open Certificate Manager.
2. Select the "CA configuration" tab.
3. Click on the application certificate under the desired device on the left and select "Delete".

Result

The application certificate is deleted.

Note

Deleting does not affect the certificate configuration installed on the device.

If necessary, delete the certificate from the device. On a Unified PC, you use Certificate Manager to do this. On a Unified Comfort Panel, use the "Security" function in the Control Panel.

Recreating an application certificate

You have the option to recreate application certificates, for example, when their runtime ends.

See section Recreating application certificates (Page 7553).

See also

Exporting certificate configuration (Unified PC) (Page 7536)

Exporting the certificate configuration (UCP) (Page 7540)

Adding devices (Page 7531)

17.5.7 Export options

The following table provides an overview of which export options WinCC Unified Certificate Manager offers and how to use them:

Option	Use	Available on the certificate authority device	Available on the Unified target device (Unified PC)
Export of the CA container	To provide the certificate configuration from one or more Unified PCs.	✓	-
Exporting the certificate configuration of a device	To make available the certificate configuration of a single Unified Comfort Panel. Can also be used to make available the certificate configuration of a single Unified PC.	✓	-
Exporting a single application certificate	To make available as a public certificate	✓	✓
Exporting the root certificate and CRL file	To establish the trust relationship between a Unified device and its external communication partners. To make available an updated CRL file	✓	-
Exporting the complete configuration of the certificate authority	To backup data of the certificate authority	✓	-

17.5.8 Exporting, importing and installing for Unified PCs

17.5.8.1 Exporting certificate configuration (Unified PC)

Introduction

Exporting the certificate configuration of a Unified PC is required in the following cases:

- After adding the device and configuring its application certificates for the first time
- After adding, deleting or recreating application certificates
- After the recreation of the root certificate
- After updating the CRL file

Note

If you only want to update the CRL file, exporting the certificate configuration is not mandatory. You can also export the CRL file individually and import it to the PC device via SIMATIC Runtime Manager.

Note

Exporting the certificate configuration is not necessary if the certificate authority device is used as a Unified HMI device and you only want to provide the modified certificate configuration of this device.

In this case, you can install the certificate configuration or individual certificates directly without exporting and importing them first.

Export options

To export the certificate configuration of a Unified PC, you can select from the following options:

- Export CA container
  The certificate configurations of all devices are exported.
- Export device
  Export only the certificate configuration of a specific Unified PC.

Note

In both cases, you can only install the certificate configuration of this PC on the Unified PC.

	Tip for an efficient procedure
Recommended procedure: • The certificate configuration of multiple devices was changed: Export the CA container. • The certificate configuration of a single Unified PC was changed: Export the certificate configuration of this device.	

Requirement

The certificate configuration of a Unified PC is completed.

Procedure

1. On the certificate authority device, open Certificate Manager.
2. Select the "CA configuration" tab.
3. Follow these steps:
   To export the certificate configurations of all devices:
   - Right-click on the root certificate.
   - Select "Export > CA container ...".

   To export only the certificate configuration of the Unified PC:
   - Right-click on the Unified PC.
   - Select "Export device > To PC".
4. Enter and repeat a password in the "Export" dialog to protect the export file.
   See also section Password requirements (Page 7521).
5. Click "Export".
6. Click on "Save" and select the storage location and the file name.

Result

The certificate configuration of the Unified PC or the certificate configurations of all devices are stored encrypted with the specified password in a secure storage file:

Next step

Import the certificate configuration to the device and install it.

See also

Importing certificate configuration (Unified PC) (Page 7538)

Add application certificates (Page 7533)

Installing certificates (Unified PC) (Page 7539)

17.5.8.2 Importing certificate configuration (Unified PC)

Note

Importing the certificate configuration is not necessary if the certificate authority device is used as a Unified HMI device, and you only want to provide the modified certificate configuration of this device.

In this case, you can install the certificate configuration or individual certificates directly without exporting and importing them first.

Requirement

- On the certificate authority device, the CA container or the certificate configuration of the device was exported.
- The Unified PC whose certificate configuration you want to import has access to the storage location of the export file.

Procedure

1. Open the WinCC Unified Certificate Manager on the Unified PC.
2. Select the "CA configuration" tab.
3. Double-click "Open configuration ...".
4. Select the export file.
5. Enter the password selected during export.
6. Confirm your entries.

Result

The configuration file is loaded to the "CA configuration" tab. The content of the tab depends on the selected export option:

- CA container exported:
  You will see the certificate configurations of all devices of the certificate authority.
  You can install only the certificates of the local device. The display of the other devices is for information purposes. You cannot change their configuration.
- Certificate configuration of the device exported:
  Display and installation are limited to the certificate configuration of the local device.

Exiting Certificate Manager closes the loaded configuration.

Next step

Install the certificates on the device.

See also

Exporting certificate configuration (Unified PC) (Page 7536)

Installing certificates (Unified PC) (Page 7539)

17.5.8.3 Installing certificates (Unified PC)

You have the option to install the entire certificate configuration of the device or individual application certificates.

Requirement

- WinCC Unified Certificate Manager is open on the Unified PC on which you want to install the certificates.
- The certificate configuration of the device has been imported to the device using Certificate Manager.
- The "CA configuration" tab is visible.

Procedure

Select one of the following options:

- To install the entire certificate configuration of the device:
  - Right-click the node of the local machine.
    The local machine has the following icon: 
  - Select "Install all certificates".
- To install a single application certificate of the device:
  - Under the local machine node, right-click the certificate.
  - Select "Install".

Result

Depending on what you have selected, the entire certificate configuration or the individual application certificate is installed.

The following applies:

- The application certificates are installed in the certificate stores defined for the respective application.
- The root certificate is trusted in each certificate store.
- The CRL file is installed in the designated certificate store.
- When a web server certificate is installed, it is automatically linked to the WinCC Unified website. The web server certificate replaces the certificate, if any, selected during the Runtime installation.
  The web page will then be restarted to enforce the use of the new certificate. Any connected web browsers will be disconnected as a result and will have to log in again.

Note

The following certificates only become effective after a restart of the WinCC Unified Runtime:

- OPC UA server certificate
- Runtime Collaboration certificate
- Audit Trail system certificate

Importing certificate configuration (Unified PC) (Page 7538)

Exporting certificate configuration (Unified PC) (Page 7536)

17.5.9 Export, import and installation for Unified Comfort Panels

17.5.9.1 Exporting the certificate configuration (UCP)

Introduction

Exporting the certificate configuration of a Unified Comfort Panel is required in the following cases:

- After adding the device and configuring its application certificates for the first time
- After adding, deleting or renewing individual application certificates
- After the recreation of the root certificate
- After updating the CRL file

Note

Alternatively, you can export the CRL file individually and import it into the Control Center of the Unified Comfort Panel using the "Security" function.

Requirement

The certificate configuration of the device is completed.

Procedure

1. On the certificate authority device, open Certificate Manager.
2. Select the "CA configuration" tab.
3. Click on the desired device on the right and select "Export device > To Panel".

4. In the dialog that opens, enter and repeat a password to protect the export file.
   See also section Password requirements (Page 7521).
5. (Optional) Adjust the number of iterations for the encryption.
6. Click "Export".
7. Select the file path and file name and click "Save".
   The data is stored in a TAR log and encrypted with the password.
8. Copy the TAR log to an external storage medium.

Next step

Import the certificate configuration to the device and install it.

See also

Add application certificates (Page 7533)

Importing and installing certificate configuration (UCP) (Page 7541)

Importing and installing certificates manually (UCP) (Page 7542)

17.5.9.2 Importing and installing certificate configuration (UCP)

Requirement

- On the certificate authority device, the certificate configuration of the Unified Comfort Panel was exported to a TAR log via "Export device > To Panel".
  See section Exporting the certificate configuration (UCP) (Page 7540).
- The TAR log was copied to an external storage medium.

Procedure

1. Connect the panel to the external storage medium.
2. Import the certificate configuration to the device.
3. Install the certificates by trusting them.

For the import and the installation, use the "Certificates" > "Import" function under "Security" in the control panel of the device.

You can find a detailed description in the "SIMATIC HMI devices Unified Comfort Panels" operating instructions.

Note

Manual importing and installing

Alternatively, you can import the certificates to the Panel manually and install them. See section Importing and installing certificates manually (UCP) (Page 7542).

17.5.9.3 Importing and installing certificates manually (UCP)

You can also import and install the certificate configuration of a Unified Comfort Panel manually instead of using the control panel of the device.

Requirement

- The certificate configuration of the Unified Comfort Panel was exported to a TAR log via "Export device > To Panel".
  See section Exporting the certificate configuration (UCP) (Page 7540).
- The TAR log was copied to an external storage medium.

Procedure

1. Decrypt the export file using OpenSSL.
   `openssl enc -d -aes256 -salt -iter <25000> -in <exportfilename> -out <tarfilename.tar> -k <password>`
   The value for the parameter `-iter` must match the iteration count specified during export.
   The decrypted TAR log contains the configured certificates in the respective application-specific folder structure.
2. Copy the file to the Panel device.
3. Manually distribute the certificates to the specific repositories of the respective application.

17.5.10 Exporting a single application certificate

With WinCC Unified Certificate Manager, you can export application certificates individually as public certificates.

Requirement

An application certificate has been added to a device in WinCC Unified Certificate Manager.

Exporting certificate to the certificate authority device

1. On the certificate authority device, open Certificate Manager.
2. Select the "CA configuration" tab.
3. Right-click on the application certificate under the device.
4. Select "Export certificate ...".
5. Select a file format.
6. Confirm your entries.
7. Select a target folder.
8. Confirm your entries.

Result

The public key of the certificate is exported. Distribute it to the external communication partners.

Export certificate on the device

Additional requirements

- The device is a unified PC.
- The application certificate has been imported into the device.

Procedure

1. On the Unified PC, open Certificate Manager.
2. Select the "Installed certificates" tab.
3. Right-click on the application certificate.
4. Select "Export certificate ...".
5. Select a file format.
6. Confirm your entries.
7. Select a target folder.
8. Confirm your entries.

See also

Add application certificates (Page 7533)

Importing certificate configuration (Unified PC) (Page 7538)

17.5.11 Exporting root certificate and CRL file

Introduction

With WinCC Unified Certificate Manager you can export and distribute root certificate and CRL file separately from the certificate configuration, as a public certificate. This is necessary in the following cases, for example:

- To establish the trust relationship between a Unified device and its external communication partners.
- To update an expired CRL file on a Unified device.

You can select between the following options:

- Exporting root certificate and CRL file
- Export the CRL file only

Note

Alternative path for Unified PCs

If the Unified device is a PC on which the root certificate and its CRL file are already installed, you can also export both files via SIMATIC Runtime Manager.

You can find additional information here (Page 7504).

Requirement

A certificate authority has been created on the certificate authority device in Certificate Manager.

Exporting root certificate and CRL file

1. On the certificate authority device, open Certificate Manager.
2. In the "CA configuration" tab, click the root certificate on the right.
3. Select "Export > CA Certificate ...".
4. Select a file format.
5. Confirm your entries.
6. Select a target folder.
7. Confirm your entries.

The root certificate and its CRL file are exported to the target folder, each to a separate file.

Export CRL file only

1. On the certificate authority device, open Certificate Manager.
2. Select the "CA configuration" tab.
3. Under the root certificate, right-click the Certificate Revocation list.
4. Select "Export".
5. Select a file format.
6. Confirm your entries.
7. Select a target folder.
8. Confirm your entries.

The CRL file is exported to the target folder.

Distribute files

After the export, distribute the files to the target devices:

- On a Unified PC you install the files with SIMATIC Runtime Manager.
- On a Unified Comfort Panel, install the files in the Control Panel under "Security" using the "Certificates" > "Import" function.
- To distribute files to external communication partners, proceed as described in the user help for the device.

See also

Creating a certificate authority and root certificate (Page 7530)

17.5.12 Installing root certificate for access via web client (Unified PC)

Using web certificates

To enable web browsers to establish a secure connection to WinCC Unified, the root certificate with which the web server certificate of WinCC Runtime was issued must be known in the web browser as a trusted certification authority.

By installing the web server certificate on the PC device, the public root certificate is made available as a download for installation in web browsers on the WinCC Unified home page.

The procedure for installing the root certificate differs depending on your web browser.

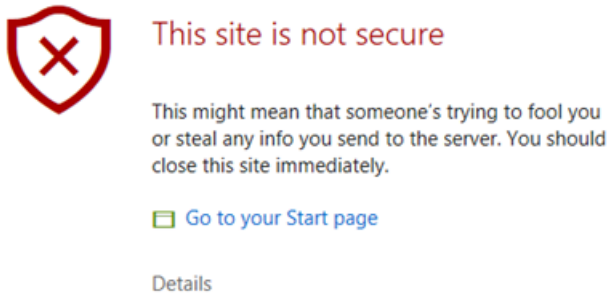
Installing the root certificate for Chrome and Microsoft Edge

Chrome and Microsoft Edge use the Windows system certificate store.

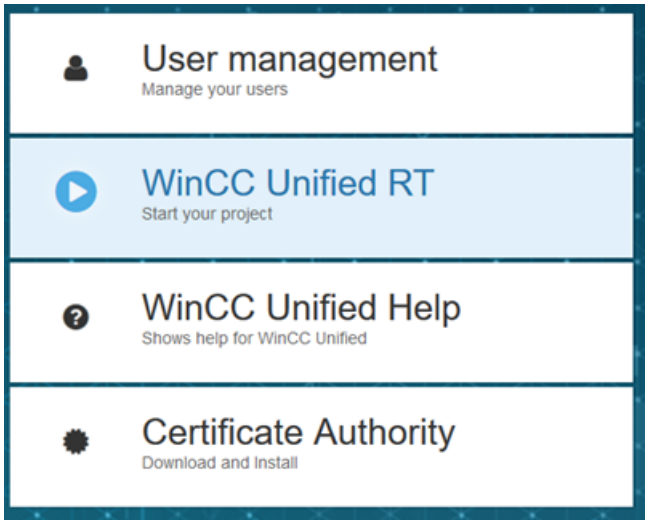
- On devices **with WinCC Unified installation** that have been configured with the Certificate Manager, these web browsers can immediately establish a secure connection to the WinCC Unified web pages because the root certificate has already been installed in the system certificate store.
- On devices **without WinCC Unified Installation** the root certificate must be installed manually.

To install manually, follow these steps (for example, Microsoft Edge):

1. Open the WinCC Unified home page via the URL https://<host name>
   At first, an error message appears:

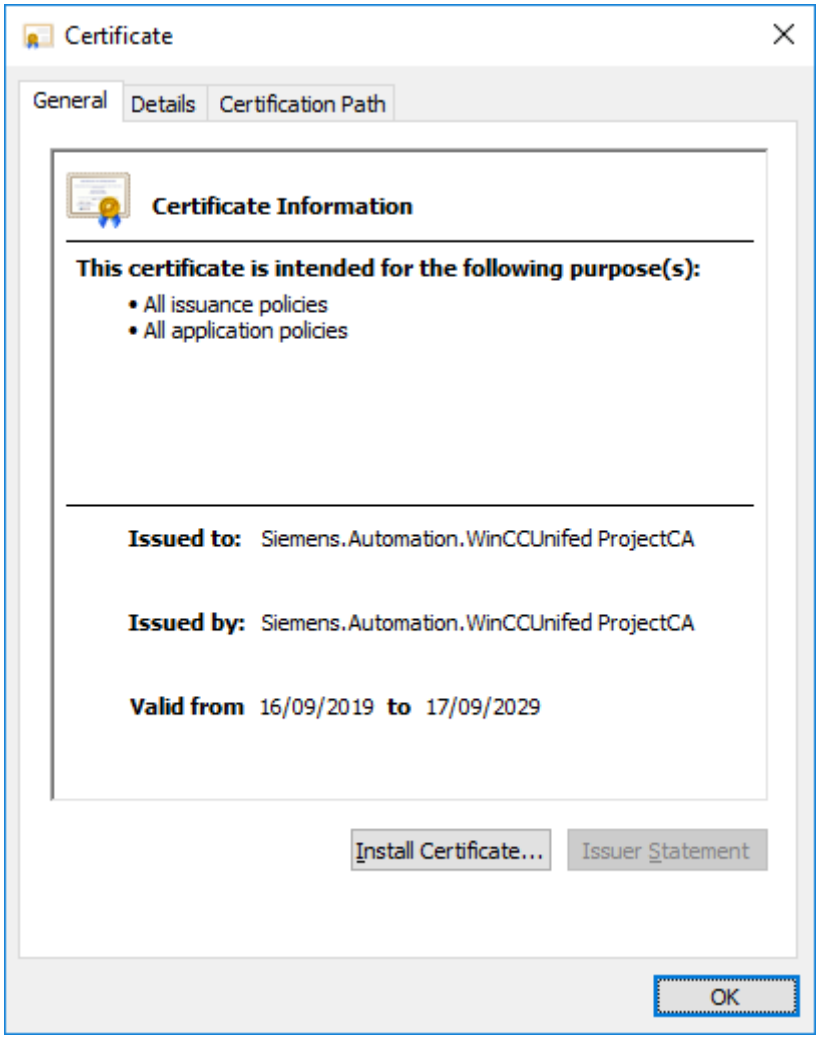


2. Open the field with the error details and confirm that you want to open the web page.
3. On the WinCC Unified home page, select the field "Certificate Authority" and confirm "Open file" in the download dialog.



The root certificate is downloaded to the default download directory.

4. Open the downloaded file.
   The root certificate is opened with the Windows standard form.



5. To import the root certificate into Windows, select "Install Certificate".
6. In the certificate import wizard, select "Local Machine" as the storage location, "Trusted Root Certification Authority" as the certificate store and start the import process.

Installing the root certificate for Firefox

Firefox uses its own certificate store and must therefore be configured manually on each device once:

1. Open the WinCC Unified home page via the URL https://<host name>
   At first, an error message appears:
2. Open the field "Advanced" and confirm the field "Accept the Risk and Continue".
   An exception is entered for this page in the Firefox certificate management.
3. On the WinCC Unified home page, select the field "Certificate Authority".

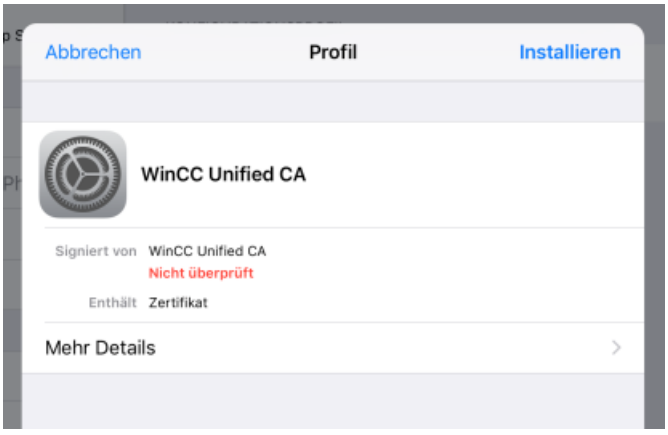
4. Save the root certificate. To do this, click "Save file" in the Firefox dialog that follows.
5. Store the certificate in the Firefox certificate store. Proceed as follows:
   - Open the "Settings" page of Firefox.
   - Select "Privacy & Security". There you will find the "Certificates" area further down. Open "Show certificates...".
   - In the "Certificate Management" window, select the "Certification authorities" tab:

   - Click "Import" and select the root certificate you saved in step 3.
   - In the window that opens, select the option "This certificate can identify websites" and confirm your selection.
   - Click "Server" and remove the exception that was created by step 2.

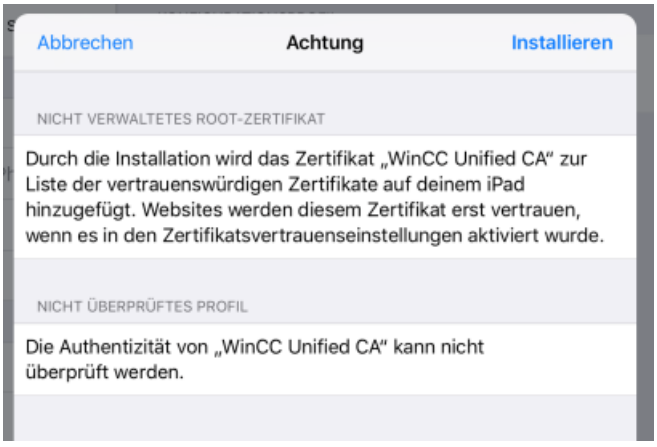
Installing the root certificate on iOS devices

iOS uses its own certificate store and must therefore be configured manually on each device once. An error message also appears when the WinCC Unified home page is opened.

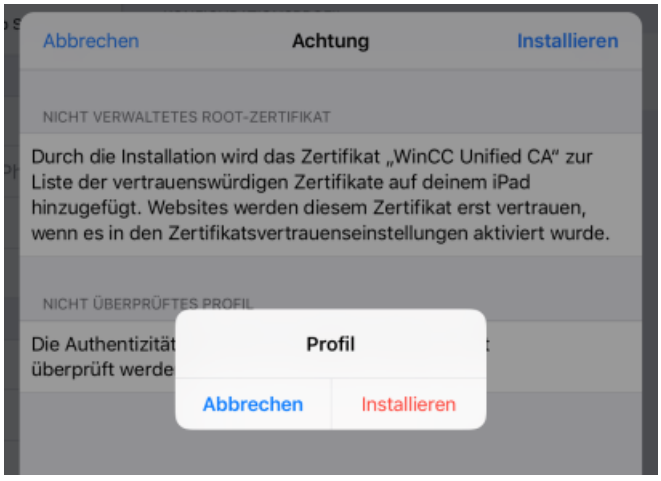
1. Open the field "Advanced" and confirm the field "Accept the Risk and Continue".
2. On the WinCC Unified home page, select the field "Certificate Authority".



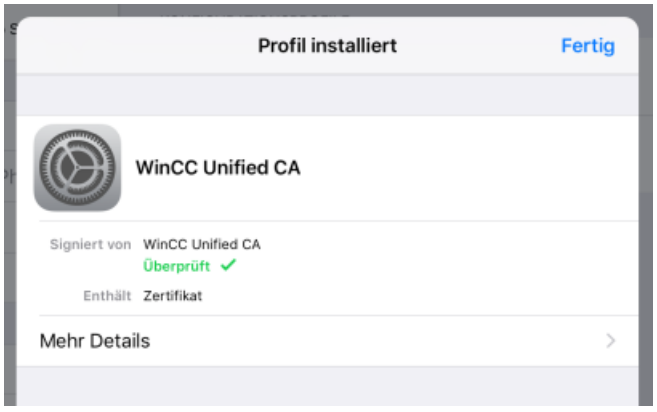
3. Select "Install".



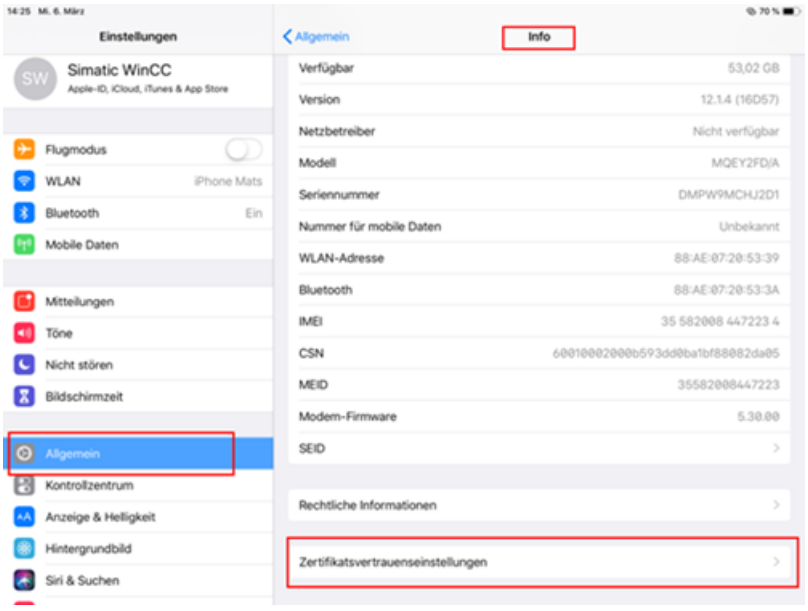
4. Select "Install" again.



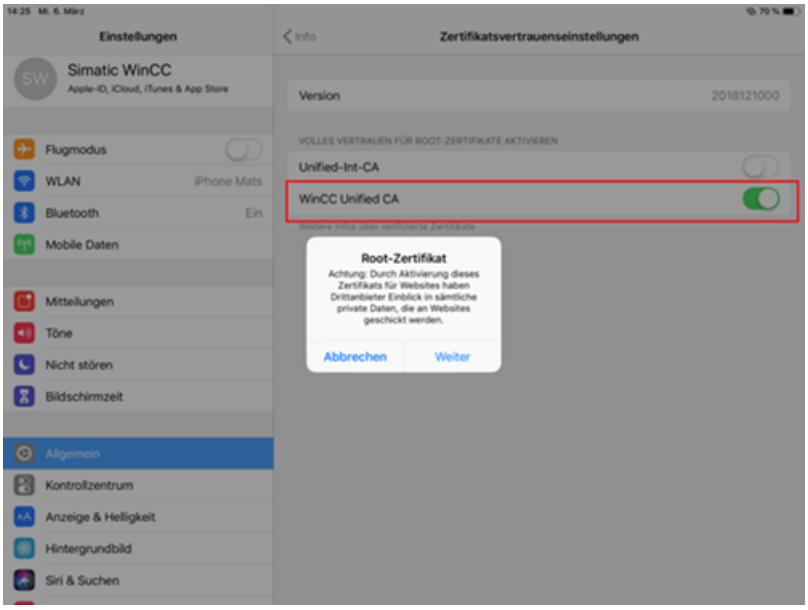
You see the entry "Trusted".



5. Select "General > Info > Certificate Trust Settings".



6. Enable "WinCC Unified CA" and select "Next".



17.5.13 Recreating certificates

WinCC Unified Certificate Manager offers the option to recreate existing certificates.

You must recreate certificates in the following cases:

Expiry of an application certificate	Recreate the application certificate.
Expiry of the root certificate	Recreate the entire configuration of the certificate authority.

Expiry of the CRL file	Update the CRL file.
Change to the IP address or the computer name of a Unified device[1]	Recreate the application certificates of the device.

[1] For a Unified PC that is used as an HMI device as well as a certificate authority device: If you have changed the computer name or the IP address, recreate the entire configuration of the certificate authority. Distribute and install it.
When the certificate authority device is not used as an HMI device, there is no need to renew the certificate configuration.

See also

Recreating application certificates (Page 7553)

Recreating the entire configuration (Page 7552)

Updating a CRL file (Page 7553)

Create backup (Page 7554)

17.5.13.1 Recreating the entire configuration

The expiration of the root certificate requires that the entire configuration of the certificate authority is created again.

Requirement

A certificate authority has been created and configured on the certificate authority device in WinCC Unified Certificate Manager.

Procedure

1. On the certificate authority device, open Certificate Manager.
2. Select the "CA configuration" tab.
   You will see the configuration of the certificate authority.
3. Right-click the root certificate and select "Recreate all".
4. The "Recreate certificate authority" dialog opens.
   The properties of the previous certificate authority are taken over as default. Change them if necessary.
5. Enter the same password as when you created the certificate authority and confirm it.
6. Click "Create".

Result

The configuration of the certificate authority is recreated:

- Private key
- Root certificate
- CRL file
- All devices and their application certificates

Next steps

- Export the certificate configuration of the devices. Import and install them on the devices.
- Distribute the root certificate and CRL file to the external communication partners.

See also

Exporting root certificate and CRL file (Page 7543)

Exporting, importing and installing for Unified PCs (Page 7536)

Export, import and installation for Unified Comfort Panels (Page 7540)

Creating a certificate authority and root certificate (Page 7530)

17.5.13.2 Recreating application certificates

In the following cases, it is necessary to recreate application certificates:

- The lifetime of a certificate has expired.
- Entries for a valid certificate are to be edited, for example to correct entries.
- The IP address or computer name of the device has been changed.

Procedure

1. On the certificate authority device, open WinCC Unified Certificate Manager.
2. Select the "CA configuration" tab.
3. Right-click on the application certificate of the desired device and select "Recreate".
   The "New <Certificate type> certificate" dialog opens. The entries of the old certificate are downloaded into the dialog.
4. Change the desired properties.
5. Click "Confirm".

Result

A new certificate is created. Export the certificate configuration of his device and install the certificate on the device.

See also

Exporting, importing and installing for Unified PCs (Page 7536)

Export, import and installation for Unified Comfort Panels (Page 7540)

17.5.13.3 Updating a CRL file

When the root certificate is created, the CRL file is given a lifetime of 24 months. When the lifetime expires, it is necessary to update the CRL file.

Requirement

A certificate authority has been created on the certificate authority device in WinCC Unified Certificate Manager.

Procedure

1. On the certificate authority device, open Certificate Manager.
2. Select the "CA configuration" tab.
3. Under the root certificate, click the "Certificate Revocation List" node on the right.
4. Select "Update".

Result

A new CRL file with a lifetime of 24 months is created.

Next step

Distribute and install the CRL file to the target devices:

- On a Unified PC, you install the file with SIMATIC Runtime Manager.
- On a Unified Comfort Panel, install the file in the Control Panel under "Security" using the "Certificates" > "Import" function.
- To distribute files to external communication partners, proceed as described in the user help for the device.

See also

Exporting root certificate and CRL file (Page 7543)

Creating a certificate authority and root certificate (Page 7530)

17.5.14 Create backup

Procedure

To create a backup copy of all the data of the certificate authority, follow these steps:

1. On the certificate authority device, open WinCC Unified Certificate Manager.
2. Select the "CA configuration" tab.
3. Click on the root certificate on the right and select "Export > Full backup".
4. To protect the backup file, enter and repeat a password in the "Export" dialog.
   See also section Password requirements (Page 7521).

5. Click "Export".
6. Click on "Save" and select the storage location and the file name.

Result

The entire configuration of the certificate authority is written to a backup file.

Loading the backup

1. Open Certificate Manager.
2. In the "CA configuration" tab, double-click the "Open configuration ..." entry.
3. Select the backup file and confirm with "Open".
4. Enter the password set when creating the backup and confirm with "Open".

Using distributed systems 18

18.1 Overview

Unified Collaboration

Unified Collaboration gives you the option to monitor and operate the runtime of an HMI device within the runtime of another HMI device.

Both HMI devices must be configured accordingly and located in one network. Unified Collaboration supports cross-project access.

To display the screens of the Collaboration device in runtime, use screen windows.

Web client

By using the web client you can access the runtime of an HMI device from any device.

Each web client is autonomous and independent of the runtime displayed locally on the HMI device. We are distinguishing here between synchronous and asynchronous functions.

SmartServer

With the "SmartServer" option you can access a Unified Comfort Panel using an application.

You activate the SmartServer in the TIA Portal in the runtime settings of the Unified Comfort Panel. You download the application to the device from which you want to access the Panel and execute it.

The user interface of the Panel is mirrored. It will give you access to the entire device including Control Panel and runtime. All actions that you are executing via the application are immediately visible on the Unified Comfort Panel.

18.2 Unified Collaboration

18.2.1 Basics

18.2.1.1 Basics

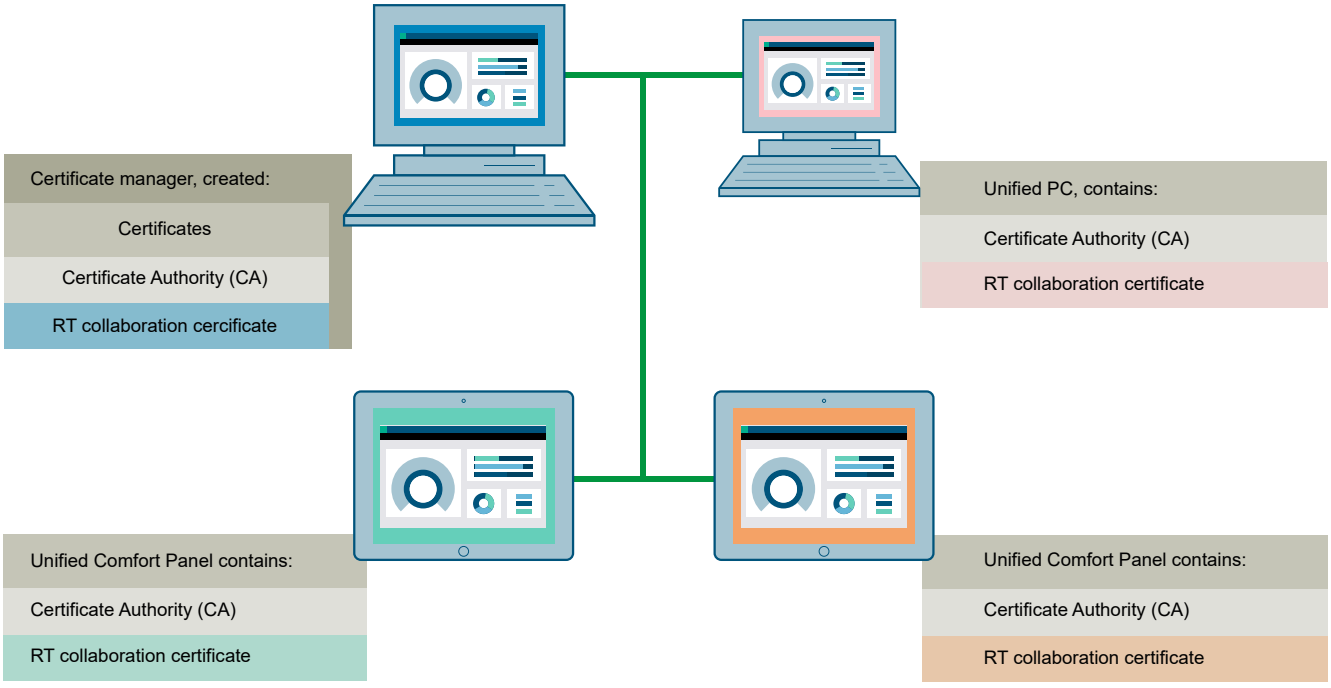
Introduction

You can use Unified Collaboration to access Unified Runtime objects, such as screens of another HMI device. You can display and operate the screens.

You use Unified Collaboration together with:

- SIMATIC WinCC Unified PC
- SIMATIC Unified Comfort Panel

The collaboration devices can be created in the same project or in different projects. The configuration steps are different for both variants.



Unified PC
Unified Comfort Panel
Screen window

Configuration steps for HMI devices in the same project

1. Create a project.
2. Add multiple HMI devices.
3. Create screens for the HMI devices.
4. Making certificates available.
5. Define collaboration settings.
6. Assign the screens to the screen windows.
7. Compile and load all HMI devices.

Configuration steps for HMI devices in different projects

1. Creating multiple projects.
2. Add multiple HMI devices.
3. Create screens for the HMI devices.
4. Making certificates available.
5. Define collaboration settings.
6. Export screen references for Unified Collaboration.
7. Import screen references for Unified Collaboration.
8. Assign the screens to the screen windows.
9. Compile and load all HMI devices.

OPC UA Collaboration

If several HMI devices operate in collaboration as OPC UA servers, the collaboration devices can read and write tags and alarms from the OPC UA servers.

Restrictions (Page 7560)

Creating certificates (Page 7564)

Configuring a screen window within a project (Page 7575)

Defining collaboration settings (Page 7572)

Configuring screen windows from different projects (Page 7577)

18.2.1.2 Requirements

To use Unified Collaboration among several devices, the following requirements must be fulfilled:

- The following software is installed on each participating device:
  SIMATIC WinCC Unified Runtime V18 (basic package, license required)

  Note

  Cross-version use of collaboration

  Screens of an HMI device with installed Runtime version V16 can be displayed in a screen window of an HMI device with installed Runtime version V17 via Unified Collaboration.

  In order that an HMI device with installed Runtime version V16 can participate in collaboration, a collaboration certificate must be created with a Certificate Manager V17 and transferred to the HMI device with installed Runtime version V16. Additional information is available under Using WinCC version compatibility.

- All devices connected via Unified Collaboration must be on the same network and have access to one another.

- Firewall settings of the Unified PC: During TIA Portal setup, the components of the Unified Collaboration are released to the firewall. The security release for the local subnet and can be adapted manually if required. Note the firewall rules "WinCC RTIL dist" and "WinCC RTIL proxy" in this regard.
  The firewall settings are relevant for the collaboration between multiple Unified PCs and for the collaboration between Unified PCs and Unified Comfort Panels.
- Local session tags are supported for V18 or later devices. In a multi-user environment, session-related data is processed independently in each local session. Data from local session tags is not saved after a session is closed.

See also

Introduction to the WinCC Unified Certificate Manager (Page 7517)

Creating certificates (Page 7564)

Using WinCC version compatibility (Page 187)

18.2.1.3 Restrictions

Note the following restrictions when using Unified Collaboration and associated Runtimes:

Screen objects

Unified Collaboration does not support all screen objects. The following screen objects cannot be used in screens that are displayed in another Runtime via Unified Collaboration:

- My controls:
  - Plant overview

System functions and scripts

Executing scripts and system functions depends on the objects used. You can find additional information in the section System functions and scripts (Page 7561).

Subsequent changes to collaboration settings

The following data must not be changed after a connection has been established:

- System ID
- Collaboration name
- IP address / Host name

Synchronicity of the system times

The system times of the interconnected HMI devices must not differ by more than 180 seconds. If the difference is greater, no connection is established between the devices.

Configured languages

The configured and activated languages for Runtime must be the same for all participating devices.

Audit

Audit is not supported in Unified Collaboration.

See also

Defining collaboration settings (Page 7572)

Configuring user management in the engineering system for Runtime (Page 6894)

18.2.1.4 User management

Collaboration supports the cross-project use of multiple users.

Note

Central user management (UMC)

If you want to use Unified Collaboration across projects, make use of central user management and the following advantages:

- Low configuration effort
- Organization of users in user groups
- High security through consistency

You can restrict access to screen objects by using function rights. You configure and manage function rights in the user management.

When you limit the operation of a screen object with a function right and make the screen object available in another HMI device using Unified Collaboration, the user logged into Runtime must have the function right through the assigned roles.

The name of the function right at the screen object is compared to the name of a function right that can be assigned to the logged in user to see whether they match. Access is granted as configured when there is an agreement. It does not matter in this case whether Unified Collaboration is used in one project or across projects.

To avoid confusion, use the same roles and function rights within a system.

18.2.1.5 System functions and scripts

Introduction

You use system functions and scripts in Unified Collaboration in the usual way. Depending on the object, there are some restrictions and special features.

Executing system functions and scripts depends on the objects used.

The objects are arranged in four categories:

- Objects of the Runtime system with system name prefix
- Objects of the Runtime system without system name prefix
- Objects related to the current session
- System functions under "HMIRuntime.Device.SysFct"

"Screen name" parameter

In system functions and scripts, you specify the "Screen name" parameter of a collaboration device in the format "Collaboration Name :: Screen name", e.g. "HMI_RT_1 :: Screen_1".

"SetPropertyValue" system function

The "SetProperty Value" system function, for example, can be used to change the "Screen" property of a screen window. For the "Value" parameter, you can specify the screen of a collaboration device in the format "Collaboration Name :: Screen name".

Note

The collaboration name and the associated screen name are not referenced in the "SetPropertyValue" system function. If you change the collaboration name or the screen name, you must adapt the system function.

Objects of the Runtime system with system name prefix

Scripts and system functions that use objects with a system name prefix are executed on the local HMI device. The objects are read from the collaboration device or written to the collaboration device.

The following objects have a system name prefix, for example:

- "Alarm"
- "AlarmLogging"
- "Tag"
- "TagLogging"
- "LoggedTag"
- "Connection"
- "PlantObject"
- "Report"
- "TextList"
- "Screen" and "ScreenItem"
- "FaceplateInterface"
- "ParameterSetTypes"

Example: Objects of the Runtime system with system name prefix

You configure two HMI devices and activate Collaboration:

- "HMI_1" with a "Screen_1" screen
- "HMI_2" with a "Screen_Collaboration" screen and "Tag_1" tag

Configure a button in the "Screen_Collaboration" screen. Configure the "SetTagValue" system function to an event of the button. Enter the following parameters:

- Tag: "Tag_1"
- Value: "1"

In the "Screen_1" screen, configure a screen window in which the "Screen_Collaboration" screen is displayed.

If Runtime is operating and the event is triggered, the system function is executed on the "HMI_1" HMI device. The value of the "Tag_1" tag changes on the "HMI_2" HMI device.

Objects of the Runtime system without system name prefix

No collaboration device can be addressed for objects without a system name prefix. The relevant system functions and scripts are executed on the local HMI device. The objects are also obtained from the local HMI device. The following objects have no system name prefix:

- "Database"
- "FileSystem"
- "Timers"
- "Traces"

Objects related to the current session

System functions and scripts that contain objects related to the current session are executed on the local HMI device. When executing the scripts and system functions, the effects will show up in the current session of the user currently logged on.

The following objects refer to the current session, for example:

- "DataSet"
- "Language"

The following system functions relate to the current session:

- "Logoff"

System functions under "HMIRuntime.Device.SysFct"

System functions under "HMIRuntime.Device" are disabled in Unified Collaboration. The following system functions cannot be used:

- "CreateScreenshot"
- "EjectStorageMedium"
- "GetBrightness"

- "GetDHCPState"
- "GetIPV4Address"
- "GetNetworkInterfaceState"
- "GetSmartServerState"
- "SetBrightness"
- "SetDHCPState"
- "SetIPV4Address"
- "SetNetworkInterfaceState"
- "SetSmartServerState"
- "ShowControlPanel"
- "ShowSoftwareVersion"
- "StartProgram"
- "StopRuntime"

See also

Restrictions (Page 7560)

18.2.2 Preparing Unified Collaboration

Below you will find out which steps are required to use Unified Collaboration. You create and distribute certificates, configure system alarms and specify the settings for collaboration.

This section includes information on the following topics:

- Creating certificates (Page 7564)
- Distributing and installing certificates (Page 7567)
- Configuring system events for Unified Collaboration (Page 7570)
- Defining collaboration settings (Page 7572)
- Changing the collaboration settings (Page 7574)

For more information, refer to the online documentation for the "Certificate Manager".

18.2.2.1 Creating certificates

Introduction

To enable collaboration between different collaboration devices, the corresponding certificates must be provided in advance. All certificates are issued by a common Certification Authority (CA) to simplify the trust relationship between the communication partners.

The root certificate of the CA is classified as trustworthy on each device for each application. When accessing WinCC Unified Runtime via websites, the root certificate must be configured as trustworthy once in the web browser.

To enable collaboration, you need a "Runtime Collaboration certificate" for each collaboration device in addition to the root certificate.

You create and manage the certificates with the WinCC Unified Certificate Manager.

Note

Renewal of the Runtime Collaboration certificate after upgrading to V18

After a Runtime Collaboration device has been upgraded to V18, its Runtime Collaboration certificate must be renewed.

Additional information is available under Using WinCC version compatibility (Page 187).

Note

Cross-version use of collaboration

Screens of an HMI device with installed Runtime version V17 can be displayed in a screen window of an HMI device with installed Runtime version V18 via Unified Collaboration.

To allow an HMI device with installed Runtime version V17 to participate in collaboration, a collaboration certificate must be created with a Certificate Manager V18 and transferred to the HMI device with installed Runtime version V17.

Creating a root certificate

1. Select a WinCC Unified PC device in your network that is to serve as the certification authority. The root certificate and the associated key are only available on this device. The configuration of additional application certificates for other devices is only possible on this device.
2. Open WinCC Unified Certificate Manager on this device.
3. Create a new root certificate. Double-click the "Create new certification authority" button.
4. Enter the properties of the root certificate in the "New certification authority" dialog. The fields are freely editable.
   Mandatory fields:
   - "Certification authority"
   - "Password" for the private key

   If necessary, select a different key length and runtime for the certificate.
5. Click "Create".

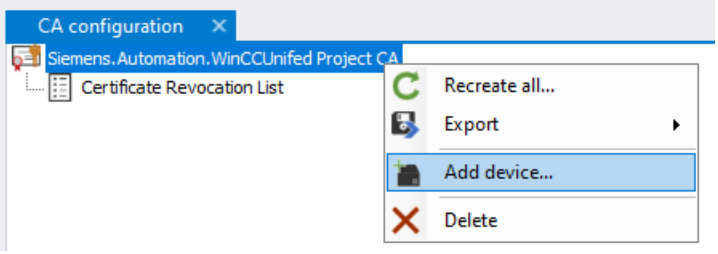
The root certificate and its key are stored on the device and used to generate the device certificates.

Note

If the "WinCC Certificate Manager" is restarted on this device, the root certificate and the device certificates generated with it are loaded automatically.

Adding devices

1. Right-click the root certificate and select "Add device ...".



2. Enter the name and/or IP address of the device in the "New device" dialog box.
   The specification of the IP address is sufficient for Unified Comfort Panel.
   For devices with dynamic IP addresses, enter only the host name.

   Note

   Permitted names

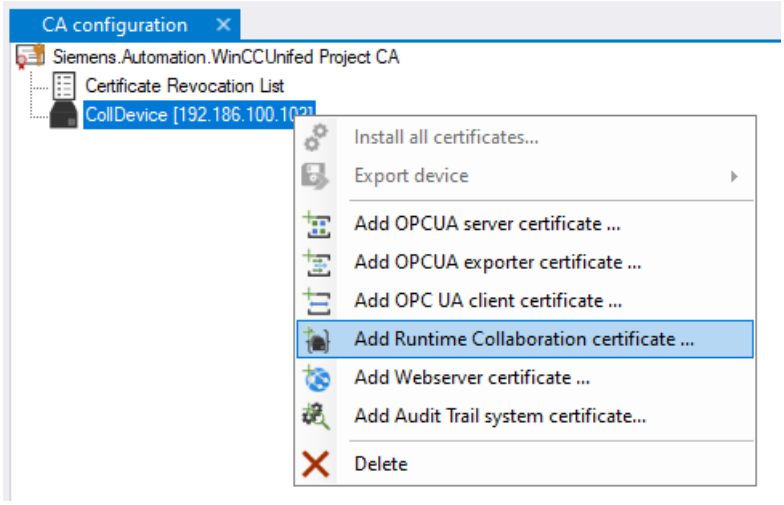
   Either the host name or the "Fully qualified domain name" can be used as the name. The name is inserted in the certificates created for the device and used for validation. To avoid validation errors when accessing the web pages, the "Fully qualified domain name" must be used within a domain.

   Using the name "localhost" is not permitted and is automatically replaced with the name of the local device by the Certificate Manager.

3. Repeat steps 1 and 2 until all collaboration devices have been added.

Adding a "Runtime Collaboration certificate"

1. Right-click on a device and select "Add Runtime Collaboration certificate ...".



2. Enter the properties of the certificate in the dialog.
   If necessary, select a different key length and runtime for the certificate.
3. Create a "Runtime Collaboration certificate" for each collaboration device.
4. If necessary, create additional certificates, e.g. web server certificates.
   You can find additional information in the "WinCC Unified Certificate Manager" operating manual.

Result

- You have created the root certificate.
- You have added all collaboration devices.
- You have added a "Runtime Collaboration certificate" for all collaboration devices.
- You have created additional certificates as required.

Basics (Page 7557)

Requirements (Page 7559)

Using WinCC version compatibility (Page 187)

18.2.2.2 Distributing and installing certificates

Introduction

To distribute the configured certificates to the corresponding devices, the certificates must be exported to a secure storage file. This file must be transferred manually to the respective device and imported there. The procedure is different for Unified PC and Unified Comfort.

Trust communication partners

For successful communication, the collaboration device must trust the root certificates of its communication partners and vice versa.

Trust relationship between collaboration devices

Collaboration devices whose certificate configuration comes from the same certificate authority automatically trust each other after the certificate configuration is installed.

Trust relationship with external communication partners

To establish the trust relationship with an external communication partner, follow these steps:

1. On the certificate authority device or on the collaboration device:
   Export the root certificate and CRL file to an external data storage medium.
2. On the external communication partners:
   - Connect the external communication partner to the external data storage medium.
   - Copy the files and trust them. To do this, proceed as described in the user help of the device.
   - Export the root certificate of the external communication partner and its CRL file to the external data storage medium.
3. Connect the external data storage medium to the collaboration device.
4. Import the root certificate and the CRL file of the external communication partner into the collaboration device and trust it:
   - Unified PC: Use SIMATIC Runtime Manager.
   - Unified Comfort Panel: In the Control Panel of the device, under "Security", use the "Certificates" > "Import" function.

During the next connection attempt, the communication partners mutually accept their application certificates.

Exporting the certificate configuration

After you have completed the certificate configuration of the devices, export the certificate configuration.

The procedures differ for PC devices and Panel devices.

Note

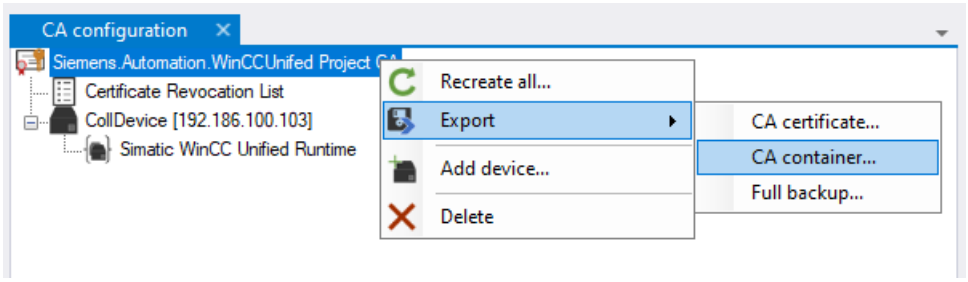
Distribution of root certificate and CRL file

Root certificate and CRL file are part of the certificate configuration of a device. They are exported or imported with the certificate configuration, installed and classified as trusted.

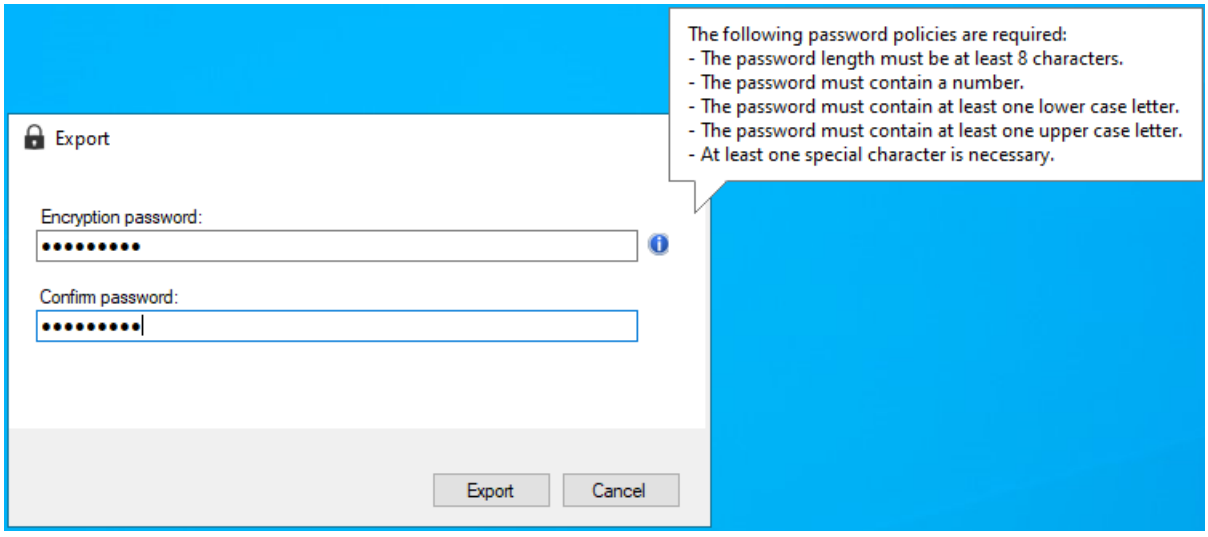
On Unified PCs, you can also export the root certificate and the CRL file via the SIMATIC Runtime Manager.

Exporting all certificates for Unified PC

1. Right-click the root certificate and select "Export..." > "CA container" in the menu.



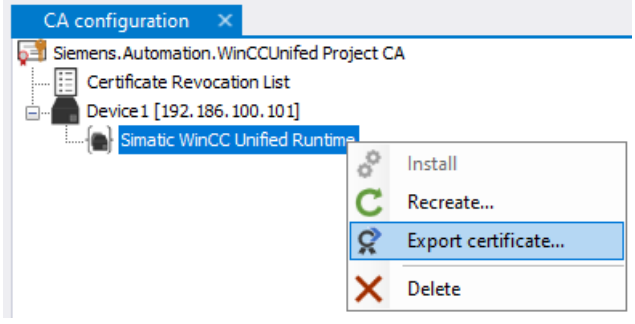
2. Assign a password in the "Export all" dialog.



3. Click on "Export" and select the storage location and file name.
   The data is stored encrypted with the specified password.

Exporting the certificate for a device

1. Right-click on the certificate and select "Export certificate" in the menu.



2. Select the format for the exported certificate.
3. Select the storage location.

Making certificates available on the Unified devices

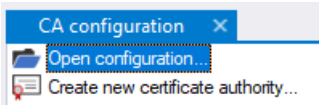
The procedures differ for PC devices and Panel devices.

Depending on the device, use the following tool:

- Unified PC: WinCC Unified Certificate Manager
- Unified Comfort Panel: Control Panel > "Security" function

To make the certificates of a Unified HMI device available on the Unified PC, follow these steps:

1. Transfer the CA container or the certificates to the Unified PC.
2. Open the Certificate Manager.
3. Import the certificate configuration.



To install an individual certificate of the device:

1. Under the local machine node, right-click the certificate.
2. Select "Install".

Result

You have distributed and installed the required certificates on all collaboration devices.

The Runtime Collaboration certificate only becomes effective after a restart of the WinCC Unified Runtime.

18.2.2.3 Configuring system events for Unified Collaboration

Introduction

An alarm log must be configured in advance in order to display system events relating to collaboration in the alarm view of a collaboration device. The alarm log supports you in identifying connection problems, for example, when a connection cannot be established due to an incorrect system ID.

Note

System events for collaboration

System events for collaboration are only available for the current HMI device and the HMI devices that you select in the collaboration settings under "Connect actively to".

Requirement

- A Unified device has been configured.

Procedure

1. Open the "Logs" editor in the project tree.
2. Switch to the "Alarm logs" tab.
3. Create an alarm log.
4. Make the required settings for the alarm log.
5. Open the "HMI alarms" editor in the project tree.
6. For the alarm class "SystemNotification", define the alarm log created in the "Log" column.
7. If required, you can define the alarm log for other classes.

Result

System events for collaboration are displayed in Runtime as logged alarms in the alarm view of the collaboration device.

The system events contain, for example, information on the connection status. Alarms for each connected device are displayed.

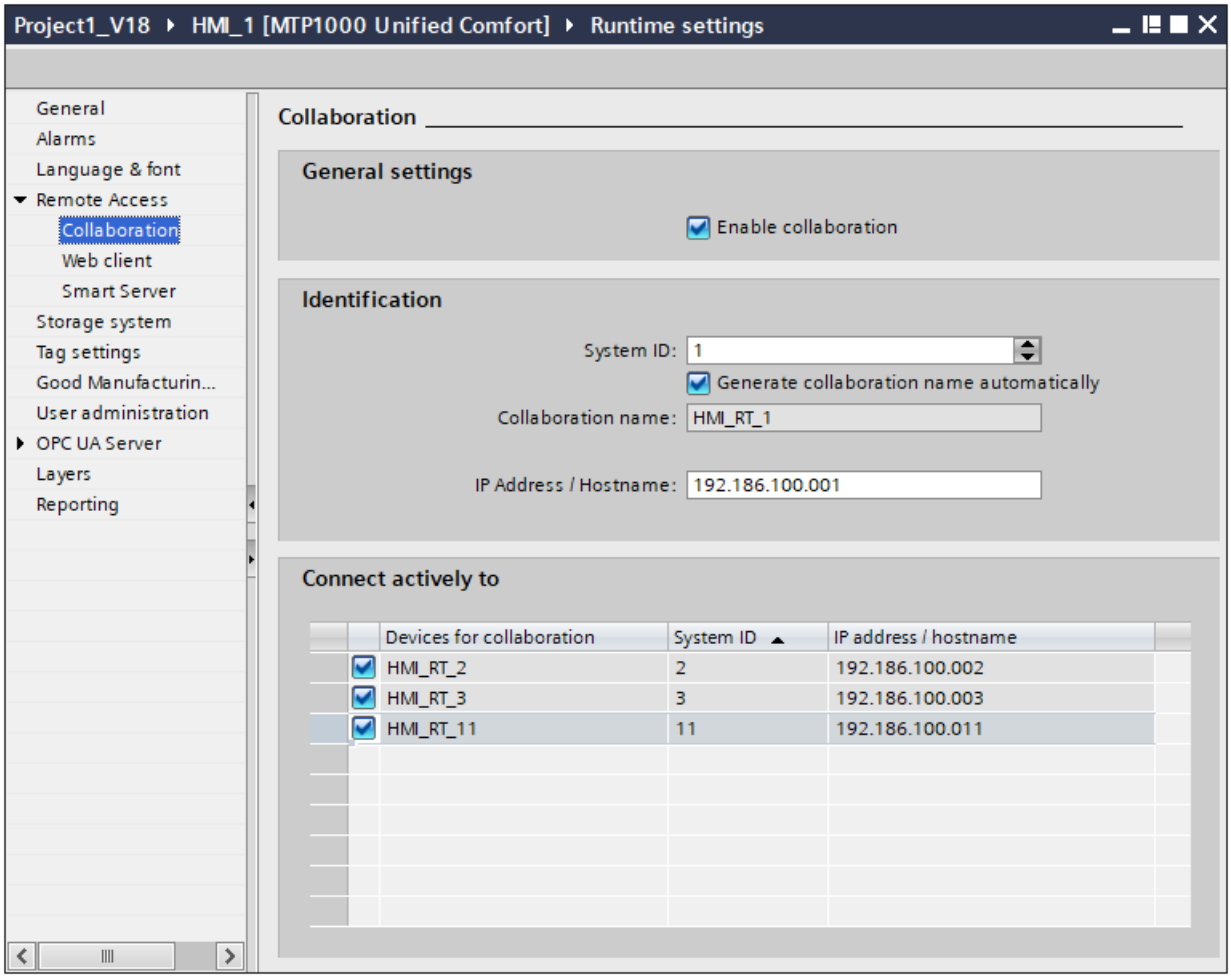
See also

Log basics (Page 837)

Logging alarms (Page 769)

18.2.2.4 Defining collaboration settings

A device must be uniquely identifiable in order for it to participate in Unified Collaboration. You make the settings in the "Collaboration" or "Remote access > Collaboration" area of the Runtime settings of the HMI device.



Identification

Note

The following information must be different for all devices participating in Unified Collaboration:

- System ID
- Collaboration name
- IP address / Host name

If a collaboration device cannot be uniquely identified in all of its information, the configuration is invalid. Errors can occur during the further configuration.

- System ID
  This ID is used for communication between the devices.
  The value can be between 1 and 2046. The system ID must be unique for devices within the project.
- Collaboration name
  If "Generate collaboration name automatically" is enabled, the collaboration name corresponds to the device name. Changes to the device name are transferred automatically.
  If "Generate collaboration name automatically" is disabled, assign the collaboration name manually. The assigned name must be unique across the system and can consist of up to 128 characters.
- IP address / Host name
  The IP address must correspond to the IPv4 format. All devices connected via Unified Collaboration must be in the same network. The IP address or the host name must be unique.

Connect actively to

Lists all HMI devices available for collaboration and shows the system ID and IP address/host name.

To select a device as collaboration device, activate the device.

Note

System events for collaboration

System events for collaboration are only available for the current HMI device and the HMI devices that you select under "Connect actively".

The system events contain, for example, information on the connection status. Alarms from each connected device are displayed. System events are displayed in the "Alarm view" control as logged alarms.

Requirement

- An HMI device has been created.

Procedure

To define the settings for Unified Collaboration, follow these steps:

1. Open the "Devices" tab in the project tree.
2. Open the Runtime settings of the respective HMI device.
3. Switch to the "Collaboration" area.
   With Unified Comfort Panel you will find the "Collaboration" area under "Remote access".
4. Select the check box "Enable collaboration" under "General settings".

5. Assign a system ID for the HMI device under "Identification".

   Note

   The system ID is incremented separately for different projects. To ensure a unique assignment, change the ID manually.

6. Specify the collaboration name.
7. Enter the IP address or the hostname of the device.
8. Select the collaboration devices under "Connect actively to".
   In order for a device to be visible under "Connect actively to", the "Enable collaboration" option must be activated for this device.

See also

Restrictions (Page 7560)

Basics (Page 7557)

Changing the collaboration settings (Page 7574)

18.2.2.5 Changing the collaboration settings

Introduction

A device must be identifiable by a unique system ID for it to participate in Unified Collaboration. When you make changes in the Runtime settings of the HMI device under "Collaboration", you must ensure that the information is valid for all devices participating in Unified Collaboration.

Note

When you change the collaboration settings of a device participating in Unified Collaboration, you must completely compile and download the projects of all participating devices.

Changing the collaboration settings

To change the collaboration settings, follow these steps:

1. Change the collaboration settings of an HMI device.
2. Check whether the following information is different for all devices participating in Unified Collaboration:
   - System ID
   - Collaboration name
   - IP address / Host name

   Invalid entries are highlighted in red.

3. If all devices participating in Unified Collaboration are in one project, follow these steps:
   – Perform a full compilation and download of the projects of all participating HMI devices.
4. If the screen references of the device whose collaboration settings were changed are made available in other projects, follow these steps:
   – Export the screen references of the HMI device.
   – Import the screen references of the HMI device into another project.
   The existing data is overwritten.
   – Perform a full compilation and download of the projects of all participating HMI devices.

See also

Defining collaboration settings (Page 7572)

Basics for downloading projects (Page 7147)
Complete reloading of a project (Page 7152)

18.2.3 Using Unified Collaboration

18.2.3.1 Configuring a screen window within a project

Requirement

- The collaboration devices are in the same network and have access to one another.
- The required certificates are provided.
- The Runtime settings of the collaboration devices are configured.
- Screens are configured for the collaboration devices.

Procedure

1. Open the screen on the device on which you want to display screens of the collaboration device.
2. Add a screen window to the screen.
3. Open the Inspector window under "Properties > Properties > General > Screen".
4. Click the selection button in the "Static value" column.
   A new dialog opens.
5. Select the collaboration device in the left area of the window.

6. Select the screen to be displayed in the right area of the window.
7. Confirm your selection.

Note

When you delete a device that is participating in collaboration, the links of its screens to the screen windows of other HMI devices are removed as well.

When the same device is to participate in collaboration again, the screens must be linked once again to the screen windows.

Using scripts

Alternatively, you can also configure screen windows via a script:

1. Perform steps 1 and 2 as described above.
2. Open the Inspector window.
3. Configure a script:
   - For an event
   - For an object property
4. Enter the following line:
   `Screen.Windows("Screen window_1").Screen = "HMI_RT_1::Screen_1";`
   Alternatively, use the snippet "Change Screen in Screen window of current screen".
5. Adapt the name of the screen window, the HMI device and the screen.
   In the example, "Screen window_1" is the screen window of the current device and "HMI_RT_1::Screen_1" is the screen of the device connected via Unified Collaboration.

Result

After compiling and downloading, the screen of the collaboration device is displayed in screen window in Runtime.

See also

Basics (Page 7557)

Restrictions (Page 7560)

18.2.3.2 Configuring screen windows from different projects

Export screen references for Unified Collaboration

Introduction

To use Unified Collaboration, the screen references of the screens that are to be available in the Runtime of another HMI device must be exported.

Once this file has been imported into a project, you can use the screens for Unified Collaboration.

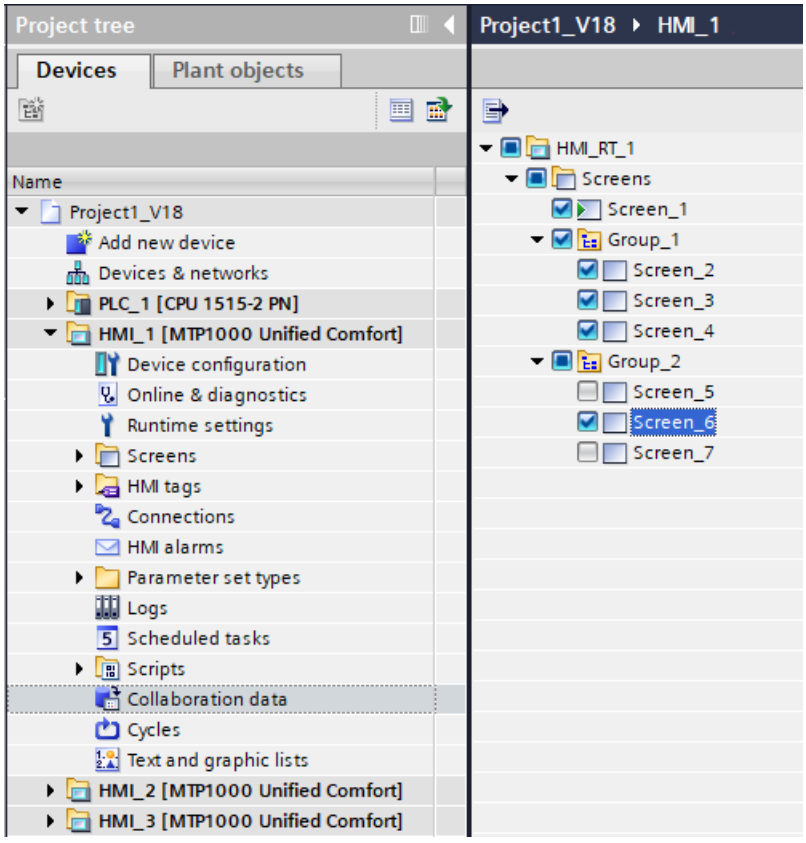
Requirement

- In the Runtime settings, the IP address or host name of the HMI device that provides the screens for collaboration is specified under "Collaboration".
- At least one screen is configured.
- The required certificates are provided.

Procedure

1. Expand the folder of the device in the "Devices" tab of the project navigation.
2. Open the "Collaboration data" editor.

3. Expand the device.
   All available screens of the device are listed.



4. Select the screens you want to export. To do this, put a check mark in the "Export" column of the screen or the group.
5. Click the export icon .

Note

If collaboration is disabled in the Runtime settings of the HMI device, the "Unified Collaboration Export" dialog appears. The export can only be continued when the entries in the Runtime settings are complete:

- System ID
- Collaboration name
- IP address / Host name

A new window opens.

6. Enter a name under which the file is to be saved.
   The "Export completed" dialog box appears.

Note

Only screen references from a single device can be exported with each export operation. To export the screen references of another device, switch to the device and repeat the operation.

Result

You have exported the screen references of the device. You can import the screens into any project.

Note

The exported xml file must not be modified manually.

Import screen references for Unified Collaboration

Introduction

To use Unified Collaboration, import screen references from collaboration devices. These devices can be either HMI devices of the same project or of another project.

Requirement

- The required certificates are provided.
- The screen references of a collaboration device are exported.

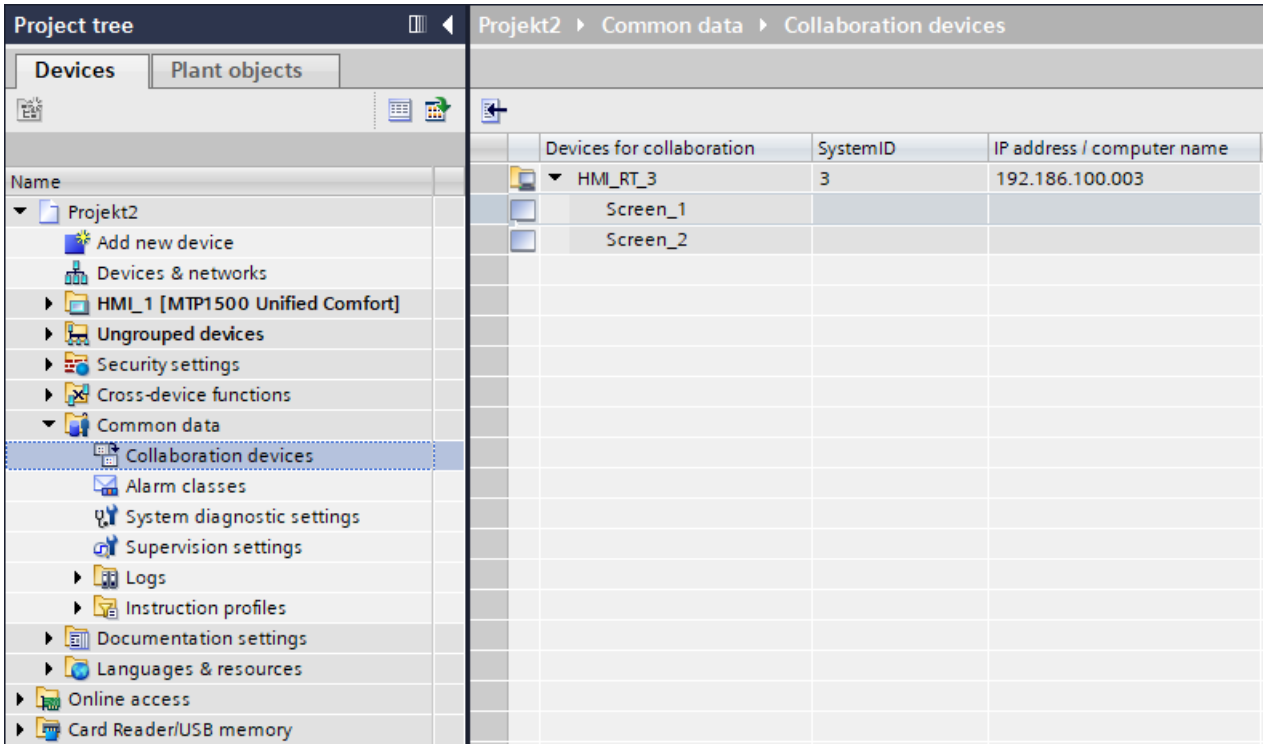
Note

The exported XML file must not be modified manually to ensure error-free import and use of the screens in Runtime.

Procedure for initial import

1. In the "Devices" tab of the project navigation, expand the "Common data" folder > "Collaboration devices".
2. Open the "Collaboration Devices" editor.
3. Click the import icon  .
   A new window opens.
4. Select the xml file you want to import.

5. Confirm all dialogs.
   The "Import completed" dialog box appears.
   The HMI device whose screen references you have imported now appears in the list.



6. Expand the list of the newly imported HMI device to see the screens.

Note

Only screen references from a single device can be imported with each import process. If you want to import the screen references of another device, repeat the procedure.

Procedure for repeated import

If you want to once again import screen references that have already been imported, the procedure is the same as for the initial import. The following collaboration settings must not differ from the previously imported device and must be unique across the system:

- Collaboration name
- System ID
- IP address / Host name

If a value is used more than once, the data import cannot be performed. The import is aborted with an error message in this case.

The previous data is overwritten by the successful import.

Deleting a collaboration device

To delete imported Unified devices from the list, click or use the "Delete" command on the shortcut menu. Individual screen references cannot be deleted. Attempting to delete a single screen reference will delete the entire device from the list.

Result

You have made the screens of a collaboration device available for Runtime of an HMI device of the project.

Note

The imported screen references of an HMI are visible to all HMI devices of the current project.

Configuring screen windows from different projects

Requirement

- Screens are configured for the collaboration devices.
- Export and import of the screen references are completed.
- All Runtime settings are configured and the collaboration devices are connected.
- The users in the participating projects are identical.

Note

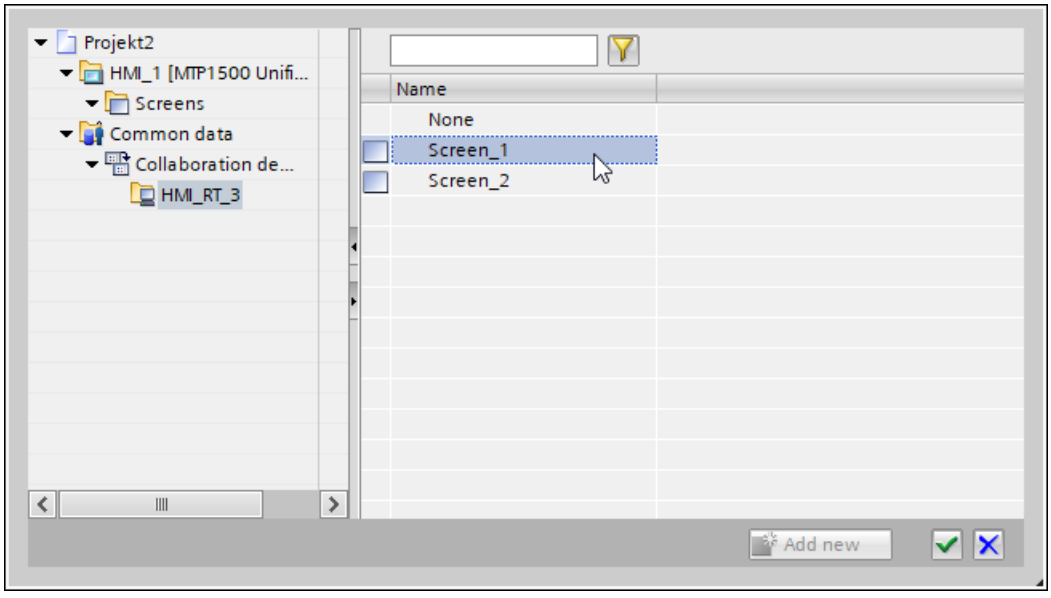
Using the central user administration (UMC)

If you want to use HMI devices in multiple projects for Unified Collaboration, use the central user administration (UMC). This reduces the configuration effort.

Procedure

1. Open the screen on the device on which you want to display screens of the collaboration device.
2. Add a screen window to the screen.
3. Open the Inspector window under "Properties > Properties > General > Screen".
4. Click the selection button in the "Static value" column.
   A new dialog opens.
5. Select the collaboration device in the left area of the window.

6. Select the screen to be displayed in the right area of the window.



7. Confirm your selection by clicking on the green check mark.

Note

When you delete a device that is participating in collaboration, the links of its screens to the screen windows of other HMI devices are removed as well.

When the same device is to participate in collaboration again, the screens must be linked once again to the screen windows.

Using scripts

Alternatively, you can also configure screen windows via a script:

1. Open the screen on the device on which you want to display screens of the collaboration device.
2. Add a screen window to the screen.
3. Open the Inspector window.
4. Configure a script:
   - For an event
   - For an object property
5. Enter the following line:
   `Screen.Windows("Screen window_1").Screen = "HMI_RT_1::Screen_1";`
   Alternatively, use the snippet "Change Screen in Screen window of current screen".
6. Adapt the name of the screen window, the HMI device and the screen.
   In the example, "Screen window_1" is the screen window of the current device and "HMI_RT_1::Screen_1" is the screen of the device connected via Unified Collaboration.

Result

After compiling and downloading, the screen of the connected HMI device is displayed in Runtime in the screen window via Unified Collaboration.

See also

Export screen references for Unified Collaboration (Page 7577)

Restrictions (Page 7560)

18.2.3.3 Display messages from participating devices

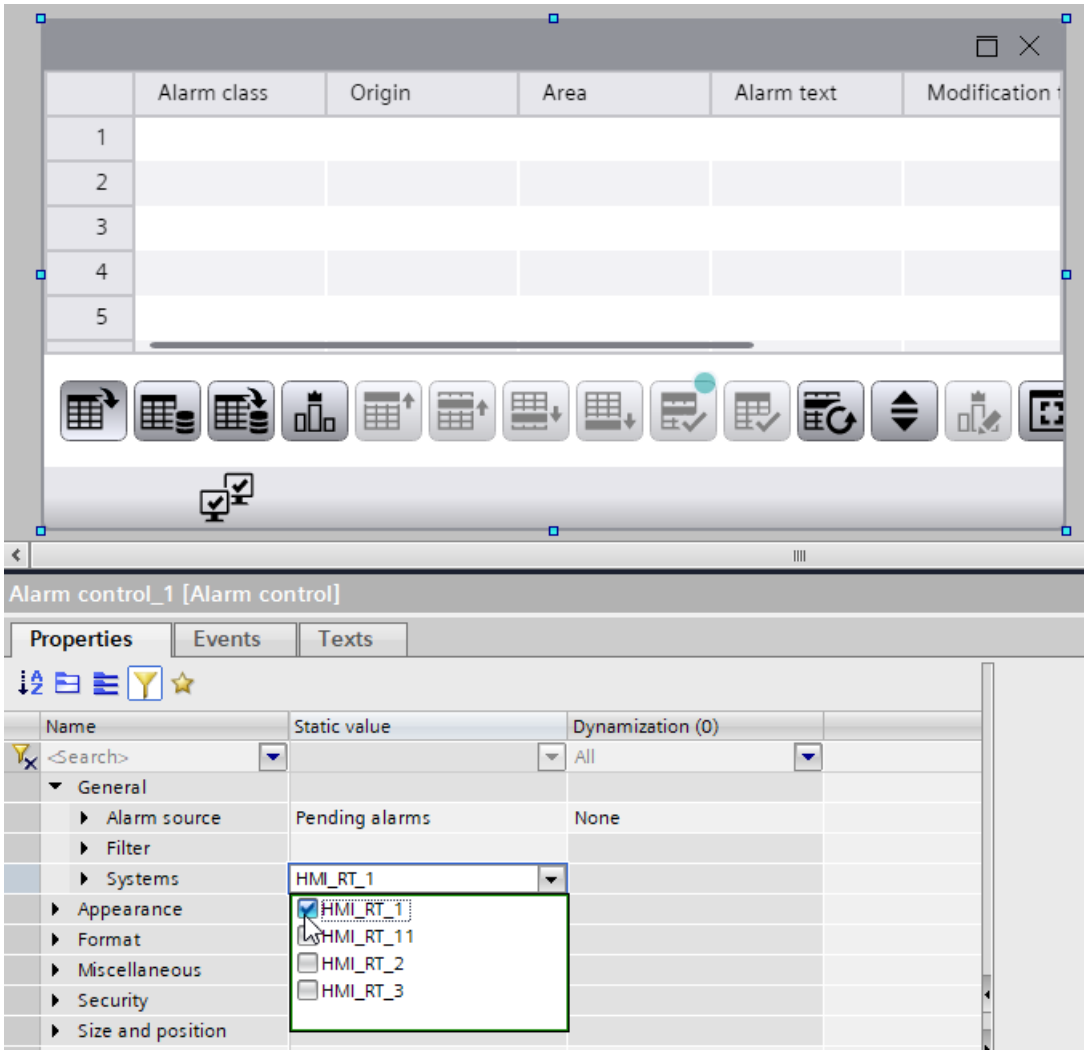
Requirement

Several HMI devices are configured as participating devices for Unified Collaboration.

Procedure

1. Configure a screen for one of the devices.
2. Place an alarm control on the screen.
3. Select the "Systems" property for the alarm control.

4. Expand the list box.
   The participating devices are displayed.
5. Enable the devices whose alarms are to be displayed.



At least one device must be selected.
Default setting: The local device is selected.

Result

In runtime, the alarm control shows the alarms from the selected participating devices.

18.2.4 Example: Connecting HMI devices from two projects with Unified Collaboration

This example shows how to access screen objects of a Unified PC and two Unified Comfort Panels using Unified Collaboration across devices and projects.

Screens of the two Unified Comfort Panels should be operable in the Runtime project of the Unified PC. One of the Unified Comfort Panels is created in another project. The screens of the Unified Comfort Panels are displayed in a screen window. You switch the display of the screens in the screen window by clicking on buttons.

Preparation

- All devices are located in a network and are uniquely identifiable.
- The Unified Collaboration components are enabled in the Windows Firewall.
- The system times of the individual devices differ by less than 3 minutes.

Create and distribute the required certificates using the Certificate Manager:

1. Open the Certificate Manager on the Unified PC.
2. Create a new root certificate for your plant.
3. Create a "Runtime Collaboration certificate" for each device.
4. Transfer the root certificate and one "RT Collaboration certificate" each to the collaboration devices.

Creating projects and adding devices

1. Create two projects: "Project1" and "Project2".
2. Configure a "PC-System_1" Unified PC in "Project1".
   "PC-System_1" is created with the HMI device "HMI_RT_1".
3. Configure a "HMI_2" Unified Comfort Panel in "Project1".
4. Configure a "HMI_3" Unified Comfort Panel in "Project2".
5. Create a "Screen_1" screen for each of the two Unified Comfort Panels.

Runtime settings of the "PC-System_1" Unified PC

1. Expand the folder "PC-System_1" in the "Project tree" under "Devices".
2. Expand the folder "HMI_RT_1".
3. Open the "Runtime settings" of the "HMI_RT_1".
4. Switch to the "Collaboration" area.
5. Activate "Enable collaboration".
6. Check and amend the following settings:
   - The "System ID" is 1.
   - "Generate collaboration name automatically" is selected.
     The "Collaboration name" is "HMI_RT_1".
     This setting cannot be changed.
   - Specify IP address or host name.
     The address must correspond to the IPv4 format.

Runtime settings of the "HMI_2" Unified Comfort Panel

1. Expand the folder "HMI_2" in the "Project tree" under "Devices".
2. Open the "Runtime settings".
3. Switch to the "Collaboration" area.
4. Activate "Enable collaboration".
5. Check and amend the following settings:
   - The "System ID" is 2.
   - "Generate collaboration name automatically" is selected.
     The "Collaboration name" is "HMI_RT_2".
     This setting cannot be changed.
   - Specify IP address or host name.
     The address must correspond to the IPv4 format.

Runtime settings of the "HMI_3" Unified Comfort Panel

1. Open "Project2".
2. Expand the folder "HMI_3" in the "Project tree" under "Devices".
3. Open the "Runtime settings".
4. Switch to the "Collaboration" area.
5. Activate "Enable collaboration".
6. Check and amend the following settings:
   - The "System ID" is 3.
   - "Generate collaboration name automatically" is cleared.
     The "Collaboration name" is "HMI_RT_3".
   - Specify IP address or host name.
     The address must correspond to the IPv4 format.

Exporting screen references

To operate the screens of the Unified Comfort Panels in the Runtime of the Unified PC, the screen references of the Unified Comfort Panel "HMI_3" must be exported from "Project2".

Follow these steps:

1. In the project tree, expand the folder of the respective devices in the "Devices" tab.
2. Open the "Collaboration data" editor.
3. Expand the device by clicking on the arrow.
   All available screens are listed.
4. Select the "Screen_1" screen. To do this, put a check mark in the "Export" column of the corresponding screen.

5. Click Export .
   A new window opens.
6. Enter a name under which the file is to be saved.
   The "Export completed" dialog box appears.

Importing screen references

To operate the screens of the Unified Comfort Panels in Runtime of the Unified PC, the screen references of the Unified Comfort Panel "HMI_RT_3" must be imported into "Project1".

To import screen references, follow the steps below:

1. In the "Devices" tab of the project navigation, expand the "Common data" folder > "Collaboration devices".
2. Open the "Collaboration Devices" editor.
3. Click Import .
   A new window opens.
4. Select the xml file you want to import.
5. Confirm all dialogs.
   The "Import completed" dialog box appears.
   The HMI device whose screen references you have imported now appears in the list.
6. Expand the list of the newly imported HMI device to see the screens.

Connecting actively to collaboration devices

Once the import of the "HMI_RT_3" collaboration device is complete, the devices must be actively connected in the Runtime settings. Follow these steps:

1. Open the Runtime settings of the "HMI_RT_1" Unified PC.
2. Switch to the "Collaboration" area.
3. Activate the collaboration devices "HMI_RT_2" and "HMI_RT_3" under "Connect actively to".
   The collaboration devices "HMI_RT_2" and "HMI_RT_3" are available for collaboration.

Configuring the screen window

In the following, a screen is configured for the Unified PC in which a screen window is inserted. Screens of the two Unified Comfort Panels can be displayed and operated in this screen window.

1. Expand the folder "PC-System_1" in the "Project tree" under "Devices".
2. Expand the folder "HMI_RT_1" and the "Screens" folder.
3. Add a screen.
   The editor of the screen opens.
4. Add a screen window.
5. Select a screen window.
6. Open the Inspector window under "Properties > Properties > General > Screen".

7. Click the selection button in the "Static value" column.
   A new dialog opens.
8. Select "HMI_2 > Screens" in the left area of the window.
9. Select the "Screen_1" screen in the right area of the window.
10. Confirm your selection.

Configuring buttons

To configure the buttons for the screen change in the screen window, follow these steps:

1. Open the screen of the "HMI_RT_1" Unified PC in which the screen window is located.
2. Configure a "HMI_2" button.
3. Configure a "HMI_3" button.
4. Select the "HMI_2" button.
5. Open the Inspector window under "Properties > Events".
6. Select the "Click left mouse button" event.
   The function list is displayed.
7. Select the "ChangeScreen" system function.
8. Open the selection window of the "Screen name" parameter.
9. Select "HMI_2 > Screens" in the left area of the window and confirm the selection.
   The "Screen name" parameter contains the value "HMI_RT_2 :: Screen_1".
10. Specify the type of "Screen window" for the "Screen window path" parameter.
11. Open the selection menu and select the screen window.
12. Select the "HMI_3" button.
13. Open the Inspector window under "Properties > Events".
14. Select the "Click left mouse button" event.
    The function list is displayed.
15. Select the "ChangeScreen" system function.
16. Open the selection window of the "Screen name" parameter.
17. Select "HMI_3 > Screens" in the left area of the window and confirm the selection.
    The "Screen name" parameter contains the value "HMI_RT_3 :: Screen_1".
18. Specify the type of "Screen window" for the "Screen window path" parameter.
19. Open the selection menu and select the screen window.

Starting Runtime

1. Compile and download all HMI devices.
2. Open Unified PC Runtime.

Result

- In Runtime, the screen of the "HMI_2" Unified Comfort Panel is initially displayed in the screen window.
- When you click the "HMI_2" button, the screen of the Unified Comfort Panel "HMI_2" is displayed in the screen window.
- When you click the "HMI_3" button, the screen of the Unified Comfort Panel "HMI_3" is displayed in the screen window.

18.3 Web Client

18.3.1 Web client basics

By using the web client you can access the runtime of a Unified PC or Unified Comfort Panel in the network from any device. The accessing device can be a PC or a smartphone, for example.

Access to the web client

By default, you use the web client for local access to your Unified PC runtime.

For Unified Comfort Panel, you must activate the web client in the TIA Portal in the Runtime settings of the Unified Comfort Panel. Alternatively, you can manage the web client directly in the Control Panel of the Unified Comfort Panel.

When you access a Unified PC or a Unified Comfort Panel for the first time, you load a certificate to enable a secure connection. Afterwards, you operate the runtime as always.

Each web client is autonomous and independent of the runtime displayed locally on the HMI device. We are distinguishing here between synchronous and asynchronous functions.

You can access a runtime simultaneously from multiple web clients.

Note

Use the latest web browser version

Use the latest version of your web browser to access the web client.

License

For remote access to a WinCC Unified Runtime with web client, you need a license depending on the HMI device used, the number and the type of accesses.

See also

Opening local user management in the "Browser" screen object (Page 6928)

18.3.2 Mode of operation of the web client

Each web client is autonomous and partially independent of other web clients and the runtime displayed locally on the HMI device. For the runtime to run without errors and expediently, we distinguish between asynchronous and synchronous functions. Some functions are not supported at all or only partially supported in the web client.

All languages configured for the runtime project are supported in the web client.

Synchronous functions

When synchronous functions are executed, the change is applied to the local runtime and in the runtime of other web clients.

Synchronous functions are all changes that change process data and project-related properties, such as:

- Change tag values
- Acknowledging alarms
- Changing log entries

Note

Changes of properties at screen objects

Properties of screen objects that were changed through a user action are not applied to the local Runtime and other web clients.

Example: Color, height and width of screen objects

Asynchronous functions

Asynchronous functions are executed independent of the local runtime and other web clients.

Asynchronous functions are mainly customizable display settings, such as:

- Change screen
- Change language
- Zoom

- Filter
- Display in screen windows

Scripts and system functions

Scripts and system functions are mainly executed on the HMI device on which the runtime is running.

A few system functions are executed on the device on which the web client is run, such as:

- "ExportParameterSets"
- "ImportParameterSets"

System functions under "HMIRuntime.Device.SysFct"

The following system functions under "HMIRuntime.Device.SysFct" are partially supported:

- "SetDHCPState":
  The "mode" parameter can be changed.
- "SetNetworkInterfaceState":
  The "adapterName" parameter can be changed.

The following device-dependent system functions under "HMIRuntime.Device.SysFct" are executed on the HMI device that is accessed via the web client. The effect of these system functions is not visible via the web client.

- "EjectStorageMedium"
- "StopRuntime"
- "ShowControlPanel"
- "ShowSoftwareVersion"
- "StartProgram"

Web client on the Unified Comfort Panel

If you want to access another HMI device from the Unified Comfort Panel using the web client, use the "Browser" control.

Option to changer user

If you use runtime locally on the Unified Comfort Panel, you will be shown an option to switch the user if you do not have sufficient functional rights. This option does not apply to access via a web client. In this case, a note about insufficient authorizations is displayed in the web client.

18.3.3 Activate web client for Unified Comfort Panel

Requirement

- A project has been created.
- A Unified Comfort Panel has been configured.

Enabling the web client in the TIA Portal

1. Open the runtime settings of the Unified Comfort Panel.
2. Expand the "Remote access".
3. Select "Web Client".
4. Enable the "Enable web access to runtime" option.
   A note about licensing is displayed.

Enabling the web client in the Control Panel

1. Open the Control Panel of the Unified Comfort Panel.
2. Select "Runtime properties > Web client".
3. Select "Enable web access to runtime".

18.3.4 Using the web client

Requirement

- The web client is enabled when a Unified Comfort Panel is used.
- The project has been compiled without errors and loaded.
- The project runs in runtime.

Procedure

To access the runtime of a different HMI device using the web client, follow these steps:

1. In the web browser, specify the IP address or the fully qualified name (name and domain) of the HMI device running runtime.
   If you want to access the runtime of a Unified Comfort Panel, use the IP address, for example "https://141.73.65.245/".
   If you are using a browser that runs directly on the HMI device, you can also use "localhost" instead of the IP address.
   To access the Runtime project directly, use "https://<ip>/device/WebRH", note the use of lowercase/uppercase letters, and use the IP address of the HMI device instead of the placeholder "<ip>".
2. If you access the runtime of the HMI device from this device for the first time and there is no corresponding certificate, you will receive a security warning. Follow these steps:
   - Continue loading the web page.
   - Select "Certificate Authority" or the symbol or the message "Not secure" in the address line of the browser.
     The certificate is downloaded.
   - Install the certificate in the web browser.
   - Reload the page.

   Note

   If you reset the time on the web client after installing the certificate so that it is before the time the certificate was created, the certificate is invalid. Install a valid certificate.

   The WinCC Unified home page is displayed.
   After complete download of a project, an error can occur when you open the WinCC Unified home page (SwacLogin).
   You can find additional information at SwacLogin: Errors after complete download (Page 7601).

   Note

   If you experience display problems in the web client, completely delete the browser data (history, form entries, etc.).

3. Select "WinCC Unified RT".
   The user login appears.
4. Enter the user name and password and select "Log in".

Result

The runtime of the remote HMI device is displayed.

The Runtime project is displayed in the language that is set in the "User login" dialog. If this language is not configured in the Runtime settings of the HMI device, the language that has the lowest number in the "Order" column under "Runtime settings > Language & font" in the TIA Portal is used.

Depending on the access authorization, you the option to monitor and operate the runtime.

Installing a certificate in the browser when accessing via web client (Unified PC) (Page 7594)
Installing a certificate in the browser when accessing via web client (UCP) (Page 7601)

18.3.5 Installing a certificate in the browser when accessing via web client (Unified PC)

Using root certificates

To enable web browsers to establish a secure connection to WinCC Unified, the current root certificate of the WinCC Runtime must be known in the web browser as a trusted certification authority.

By installing the web server certificate on the PC device, the public root certificate is made available as a download for installation in web browsers on the WinCC Unified home page.

The procedure for installing the root certificate differs depending on your web browser.

Use of self-signed certificates

As an alternative to the root certificate, you can use a self-signed certificate.

NOTICE
Security risk from self-signed certificate A self-signed certificate is not issued by a trusted certification authority. If you use a self-signed certificate from an untrustworthy source, the data transfer is not protected from attacks. Before using self-signed certificates, check the source. Depending on the firewall and network settings, the use of self-signed certificates may be prohibited.

The installation of self-signed certificates is not supported by all web browsers. Depending on the web browser, it is possible to define exceptions.

For more detailed information, refer to the operating instructions of the web browser.

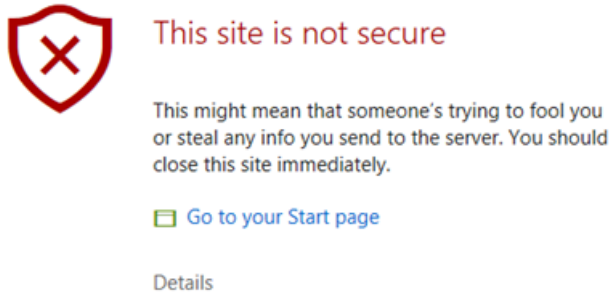
Installing the root certificate for Chrome and Microsoft Edge

Chrome and Microsoft Edge use the Windows system certificate store.

- On devices **with WinCC Unified installation** that have been configured with the Certificate Manager, these web browsers can immediately establish a secure connection to the WinCC Unified web pages because the root certificate has already been installed in the system certificate store.
- On devices **without WinCC Unified Installation** the root certificate must be installed manually.

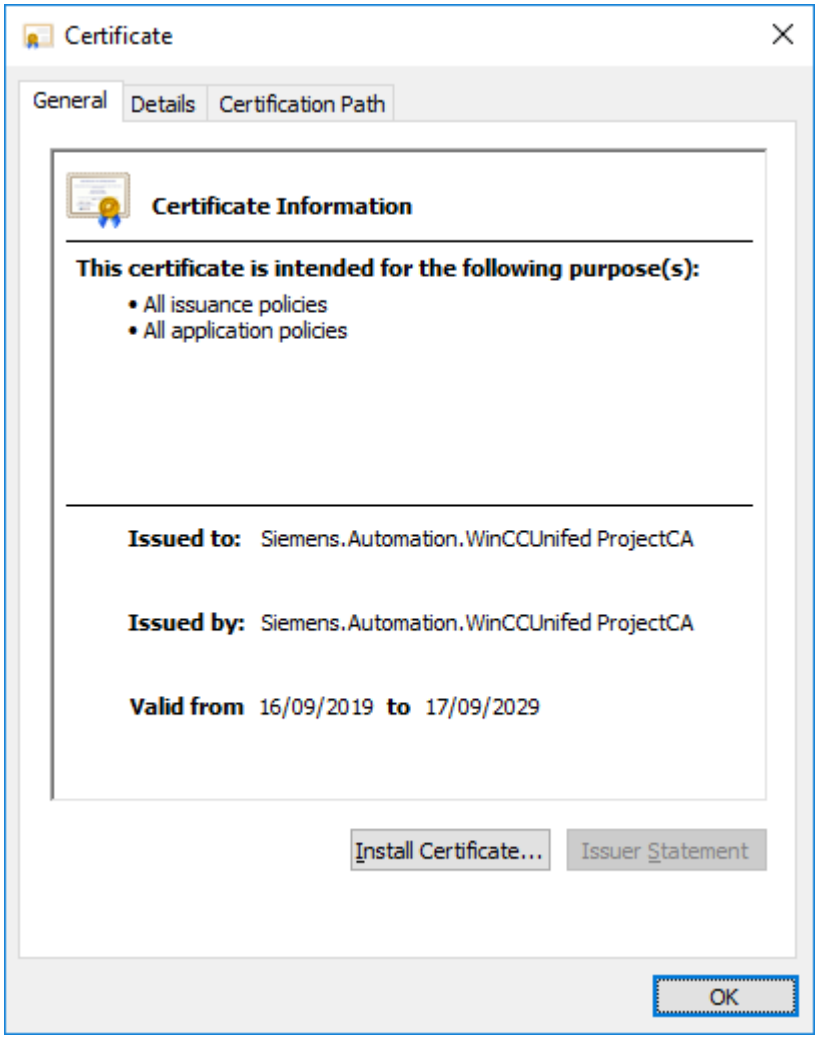
To install manually, follow these steps (for example, Microsoft Edge):

1. Open the WinCC Unified home page via the URL https://<host name>
   At first, an error message appears:



2. Open the field with the error details and confirm that you want to open the web page.
3. On the WinCC Unified home page, select the field "Certificate Authority" and confirm "Open file" in the download dialog.
   The root certificate is downloaded to the pre-selected download directory.

4. Open the downloaded file.
   The root certificate is opened with the Windows standard form.



5. To import the root certificate into Windows, select "Install Certificate".
6. In the certificate import wizard, select "Local Machine" as the storage location, "Trusted Root Certification Authority" as the certificate store and start the import process.

Installing the root certificate for Firefox

Firefox uses its own certificate store and must therefore be configured manually on each device once:

1. Open the WinCC Unified home page via the URL https://<host name>
   At first, an error message appears:
2. Open the field "Advanced" and confirm the field "Accept the Risk and Continue".
   An exception is entered for this page in the Firefox certificate management.
3. On the WinCC Unified home page, select the field "Certificate Authority".

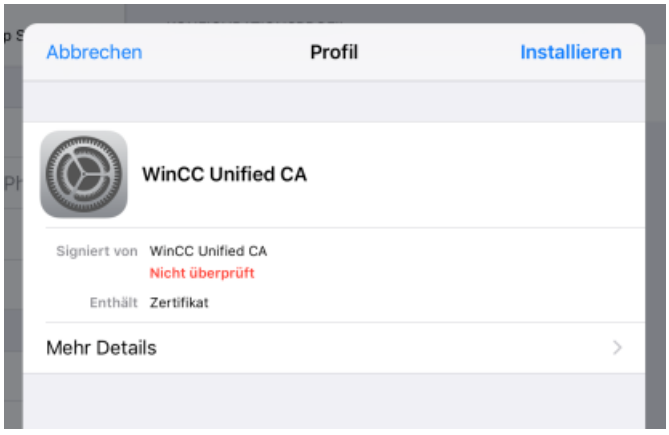
4. Save the root certificate. To do this, click "Save file" in the Firefox dialog that follows.
5. Store the certificate in the Firefox certificate store. Proceed as follows:
   - Open the "Settings" page of Firefox.
   - Select "Privacy & Security". There you will find the "Certificates" area further down. Open "Show certificates...".
   - In the "Certificate Management" window, select the "Certification authorities" tab:

   - Click "Import" and select the root certificate you saved in step 3.
   - In the window that opens, select the option "This certificate can identify websites" and confirm your selection.
   - Click "Server" and remove the exception that was created by step 2.

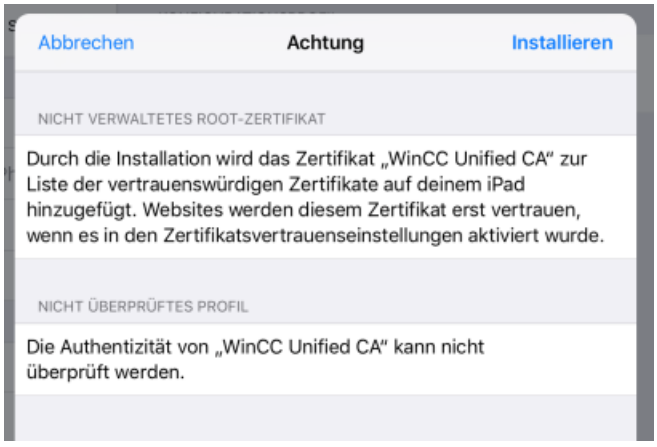
Installing the root certificate on iOS devices

iOS uses its own certificate store and must therefore be configured manually on each device once. An error message also appears when the WinCC Unified home page is opened.

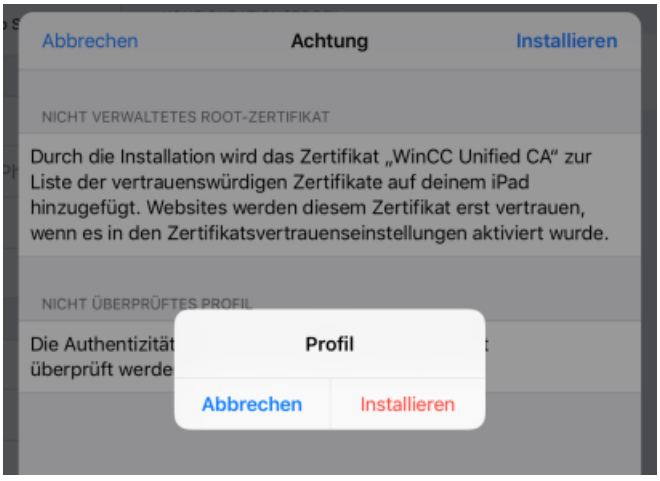
1. Open the field "Advanced" and confirm the field "Accept the Risk and Continue".
2. On the WinCC Unified home page, select the field "Certificate Authority".



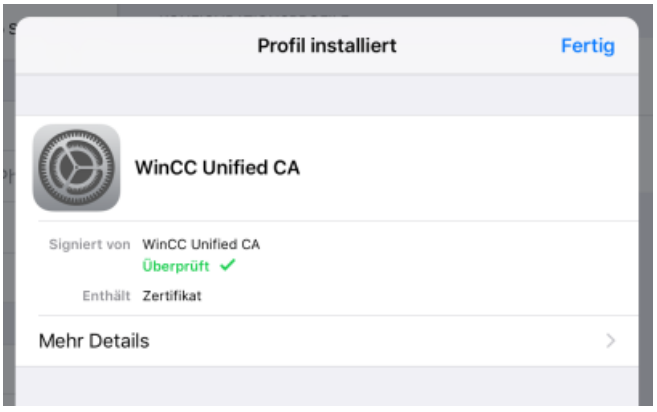
3. Select "Install".



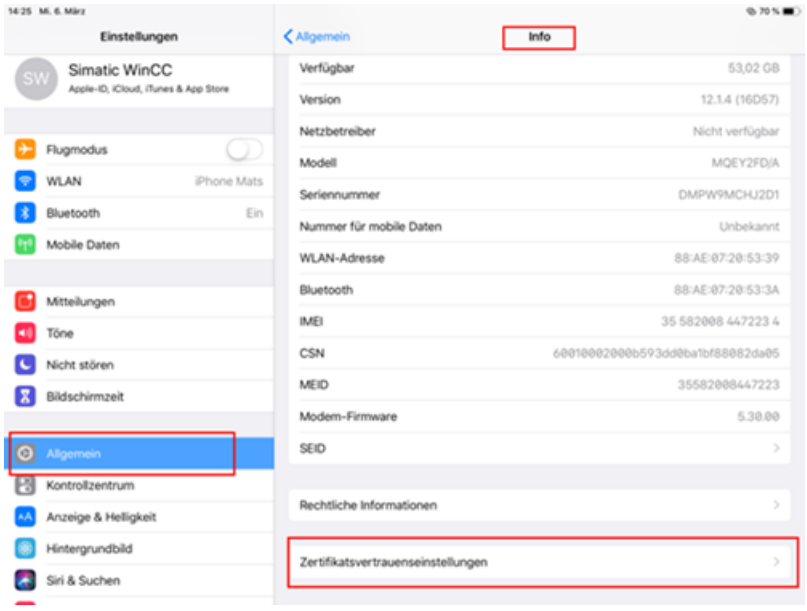
4. Select "Install" again.



You see the entry "Trusted".



5. Select "General > Info > Certificate Trust Settings".



6. Activate "WinCC Unified CA" and select "Next".

Using the web client (Page 7592)

18.3.6 Installing a certificate in the browser when accessing via web client (UCP)

Using the web server certificates

To enable web browsers to establish a secure connection to the Runtime of the Unified Comfort Panel, the certificate in the web browser must be known as trusted.

The procedure for installing the certificate differs depending on your web browser.

Use of self-signed certificates

When accessing the Unified Comfort Panel via web client, a self-signed certificate is used.

NOTICE
Security risk from self-signed certificate
A self-signed certificate is not issued by a trusted certification authority.
If you use a self-signed certificate from an untrustworthy source, the data transfer is not protected from attacks.
Before using self-signed certificates, check the source.
Depending on the firewall and network settings, the use of self-signed certificates may be prohibited.

The installation of self-signed certificates is not supported by all web browsers. Depending on the web browser, it is possible to define exceptions.

For more detailed information, refer to the operating instructions of the web browser.

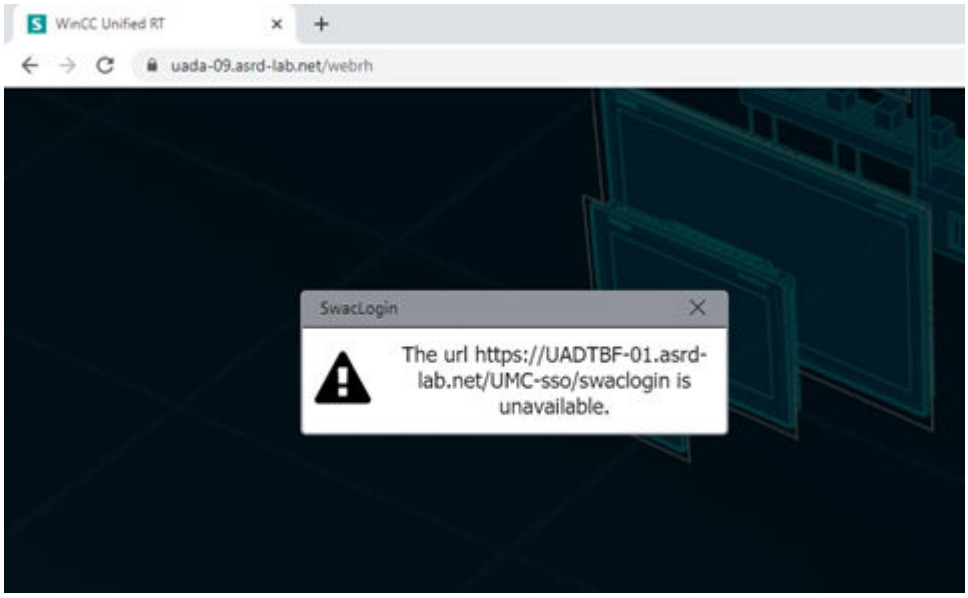
18.3.7 SwacLogin: Errors after complete download

After complete download of a project to a Unified PC, an error can occur when you open the WinCC Unified home page. The error can occur regardless of whether you open the home page locally on the PC or from a different device.

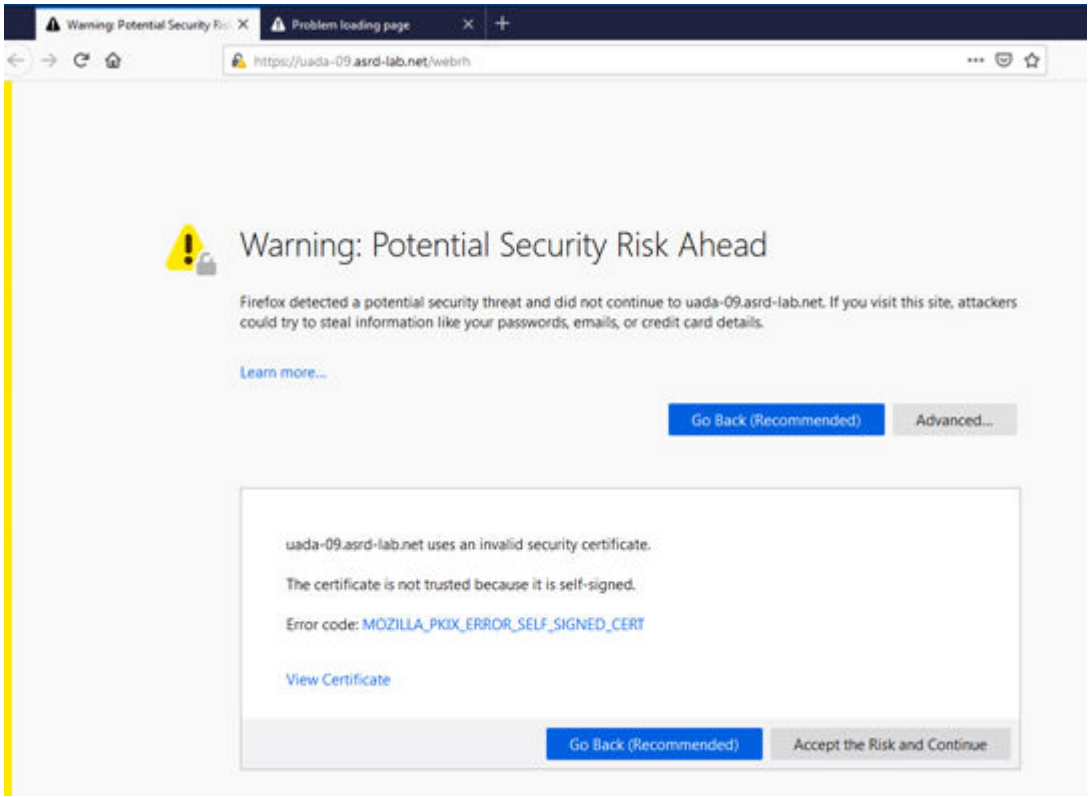
A possible cause of the error is the deletion of the browser cache.

Error description

In "Chrome" and "MS Edge", the error is displayed with the following alarm:



In "Firefox", the error is displayed with the following alarm:

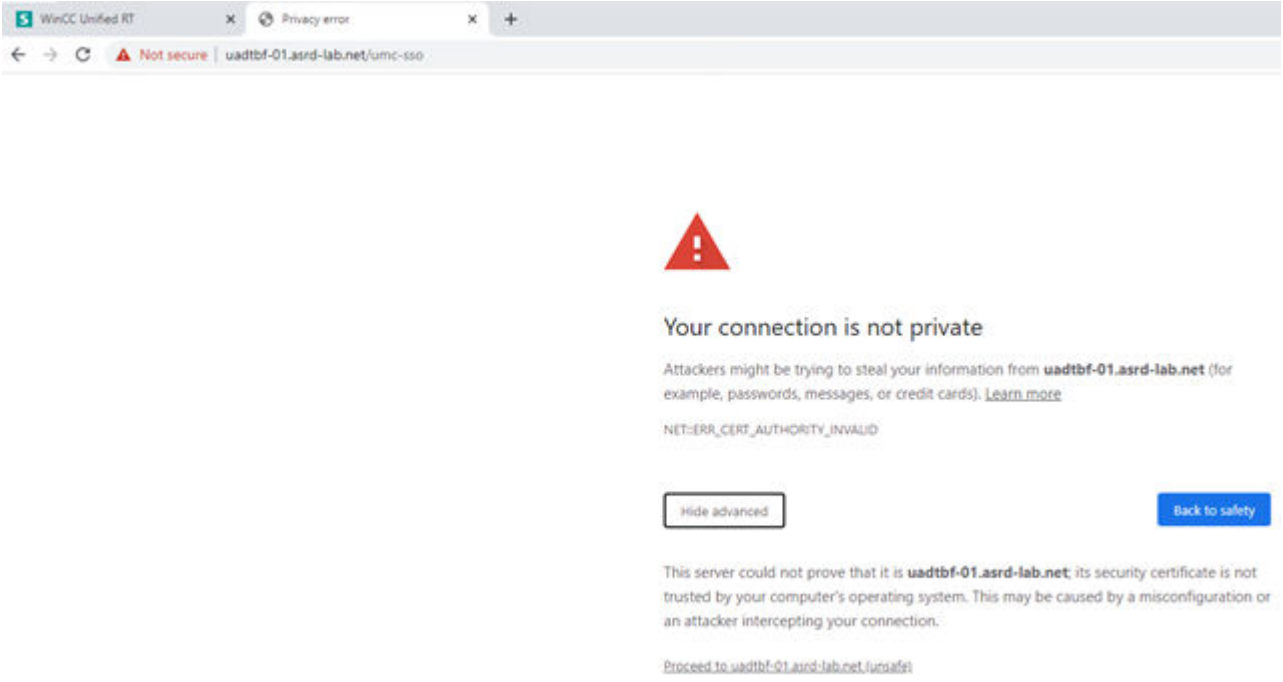


After accepting the warning of a potential security risk, the page remains empty in Firefox. Only the background screen is visible.

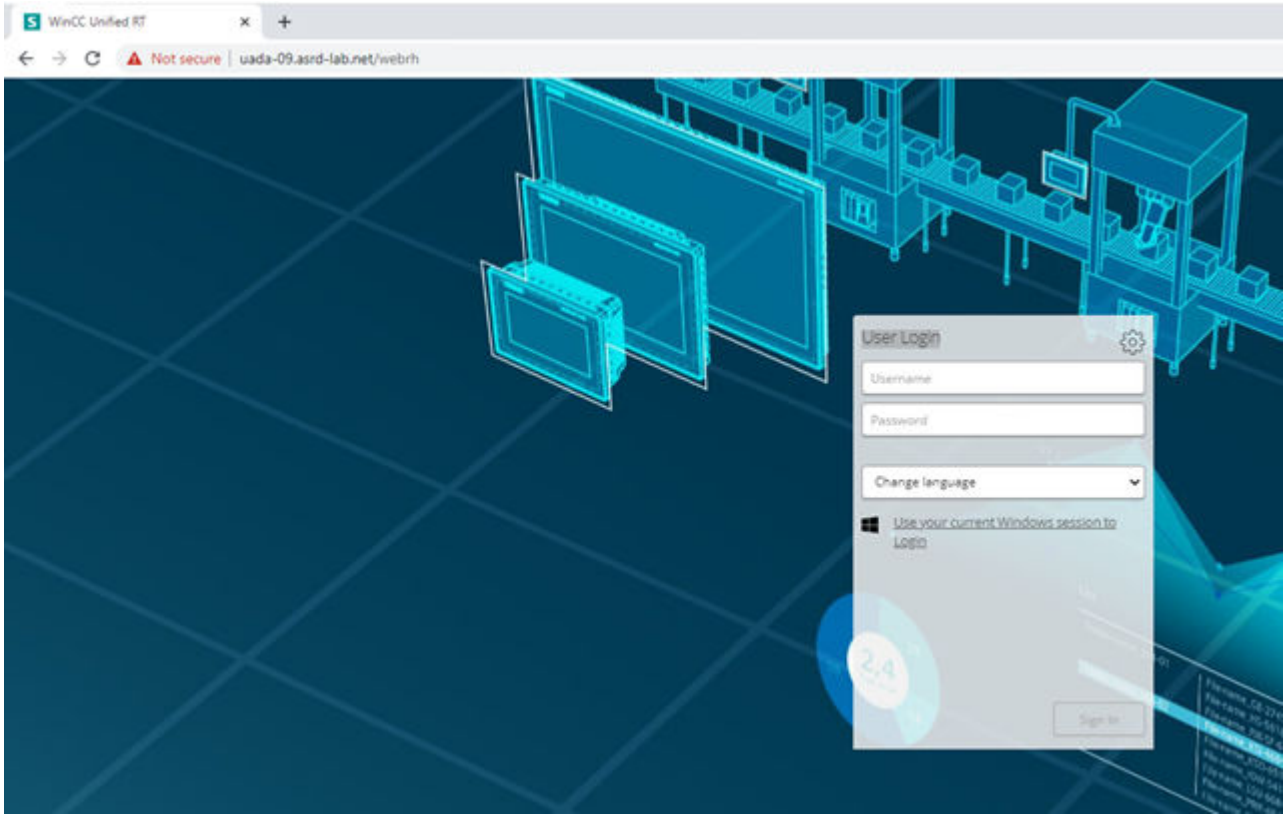
Remedy the error in "Chrome" and "MS Edge"

To remedy the error in "Chrome" and "MS Edge", follow these steps:

1. Open a new tab.
2. Enter the URL address of the identity provider of the UMC server in the address line of the browser. The URL is the same as the one in the error message without "/swaclogin", for example, "https://uadtbf-01.asrd-lab.net/umc-sso".
3. The page with a warning regarding the secure connection is displayed.



4. Accept the warning by clicking on "Proceed to uadtbf-01.asrd-lab.net (unsafe)".
5. The home page with the "User login" dialog is displayed.



Remedy the error in "Firefox"

To remedy the error in "Firefox", follow these steps:

1. Open a new tab.
2. Enter the URL address of the identity provider of the UMC server (ring server) in the address line of the browser, for example, "https://uadtbf-01.asrd-lab.net/umc-sso".
3. A blank page opens. Close the page.
4. Refresh the home page with the function key <F5>. The home page with the "User login" dialog is displayed.

Using the web client (Page 7592)

18.3.8 Logging out user

If you want to end your Runtime session, you have the following options to log out completely:

- Use the "Logout" system function.
- Log out in the user management.
- Close all instances, i.e. open windows, of the browser in use.

Requirement

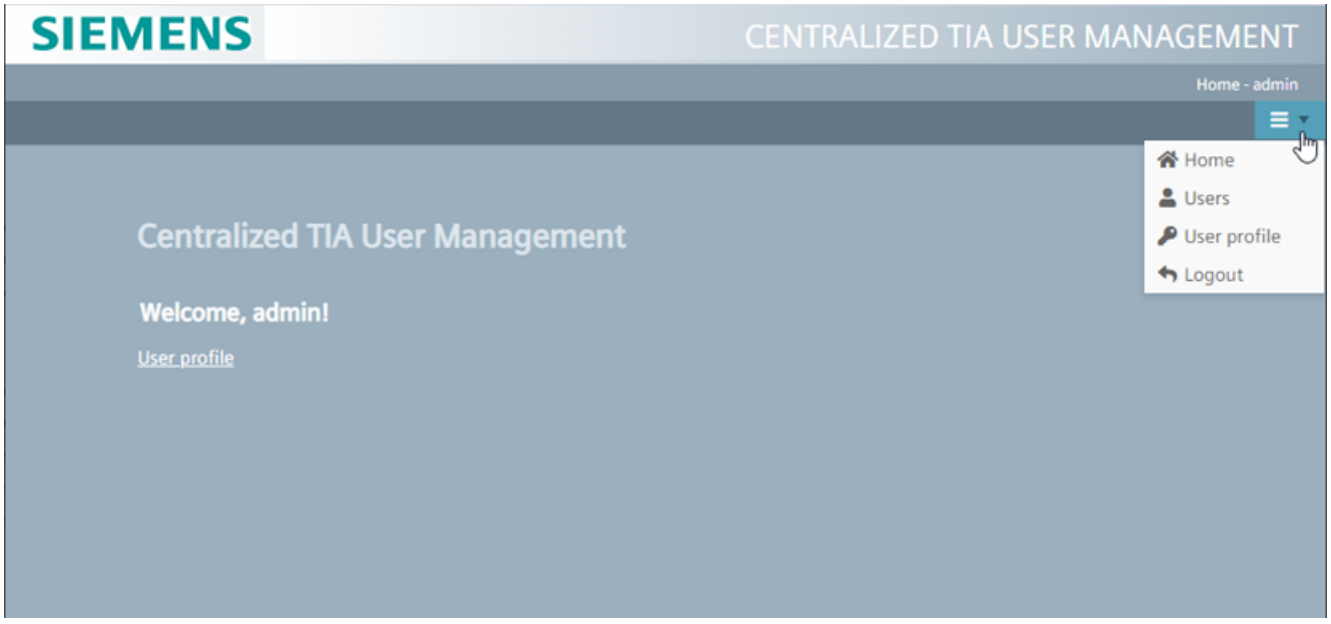
- You are logged in to Runtime.
- When you want to log out in the Runtime project, the system function "Logout" is configured, for example, to the event "Click left mouse button".

Logging out in the Runtime project with the system function "Logout"

- Select the button at which the system function "Logout" is configured.

Logging out in the user management

- Select "Logout" from the menu.
  Your session is ended.



New data downloaded from the TIA Portal is applied during the next login.

18.4 WinCC Smart Server

18.4.1 General

Introduction

With WinCC Smart Server, you can communicate between and with HMI systems via TCP/IP connections (e.g. LAN).

You can use the Smart Server in combination with SIMATIC Unified Comfort Panels.

Use of the SmartServer

You use Smart Server in the following application scenarios:

- Distributed HMI devices with Smart Client applications for controlling large machines or machines that are spread out over a large area.
- Remote control of an HMI device via the Internet or Intranet

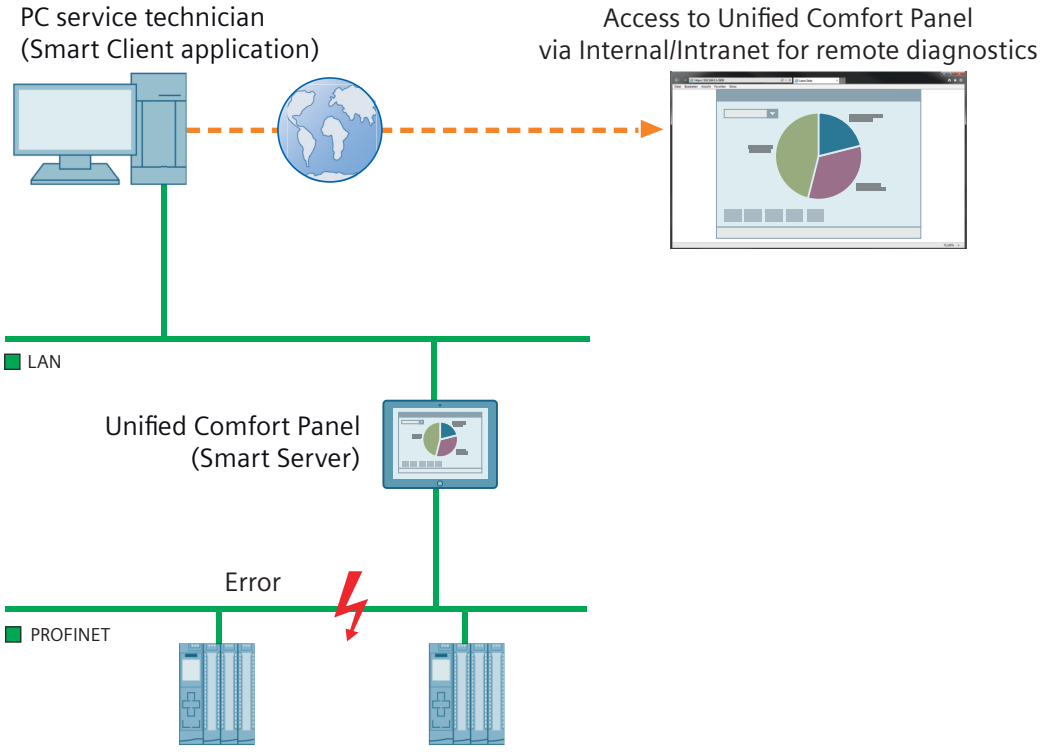
User benefits:

- Flexible solution for access to HMI devices from any location
- Reduction of load on the field bus:
  For example, Unified Runtime and Unified Comfort Panels provide a control system with access to process data. No load is placed by the factory level on the sensitive field level with respect to the necessary communication requirements. These requirements are handled by Unified Runtime as well as with the Unified Comfort Panels.
- Expensive on-site service visits to be avoided by using the remote control. Unplanned non-operation periods are reduced and the system productivity is increased.

18.4.2 Application scenarios

Remote diagnostics

A factory has a service contract with an external service company. The Unified Comfort Panel and the service technician's PC are linked together over a TCP/IP-ready network. The service technician accesses the Unified Comfort Panel via the Internet and executes remote diagnostics.



Application example

Among other things, flow rates are measured in the process control of a cooling unit. Contamination in a feed line reduces the flow of coolant. When the flow rate drops below the configured threshold value, the Unified Comfort Panel displays a warning.

The service technician then establishes a connection with the remote Unified Comfort Panel and takes the appropriate actions.

Advantage: The downtime is reduced to a minimum by remote maintenance.

Distributed HMI devices

Distributed devices, so-called Smart Clients, are used for controlling large machines or machines that are spread out over a large area.

The Smart Client establishes the connection to the Smart Server via the Smart Client application.

The operator can control and monitor the system with the Smart Client application and the Unified Comfort Panel. The operator sees the same screen with each Smart Client application and on the Unified Comfort Panel.

18.4.3 Security concept for the Smart Server

Remote monitoring and remote control of the Smart Server is protected by two functions:

- Encryption of communication with the Smart Server
- Passwords

Passwords for the Smart Server

Remote monitoring and remote control of the Smart Server is password protected. You create a password for each of two users.

- A password consists of exactly 8 characters.
- It contains at least one number (0-9)
- It contains at least one lowercase letter (a-z)
- It contains at least one uppercase letter (A-Z)
- It contains at least one of the following characters:
  !$%&()*+,-./:;<=>?@[\]_{|}~^
- Passwords cannot be entered using copy & paste.
- The passwords for User1 and User2 cannot be identical.
- Passwords must not be empty.

Note

Passwords for the Smart Server

No passwords have been preset.

You cannot use Smart Server if both passwords are not assigned.

Encrypt communication to the Smart Server

The option "Secure communication via self-signed certificates" enables an encrypted connection between Smart Client and Smart Server. When establishing the communication, the Smart Server sends a self-signed certificate to the Smart Client. The certificate must be accepted by the Smart Client.

Connections on Smart Client to Smart Server are then only possible on the basis of the exchanged certificate.

18.4.4 Settings in the TIA Portal

Introduction

In the "Runtime settings" editor, you configure the requirements for using the Smart Server.

As an alternative, configure the settings in the Control Panel of the Unified Comfort Panel.

Note that the settings on the Unified Comfort Panel are overwritten when a project is downloaded from the TIA Portal.

Requirement

- A project is open in the TIA Portal.
- A Unified Comfort Panel has been created.

Procedure

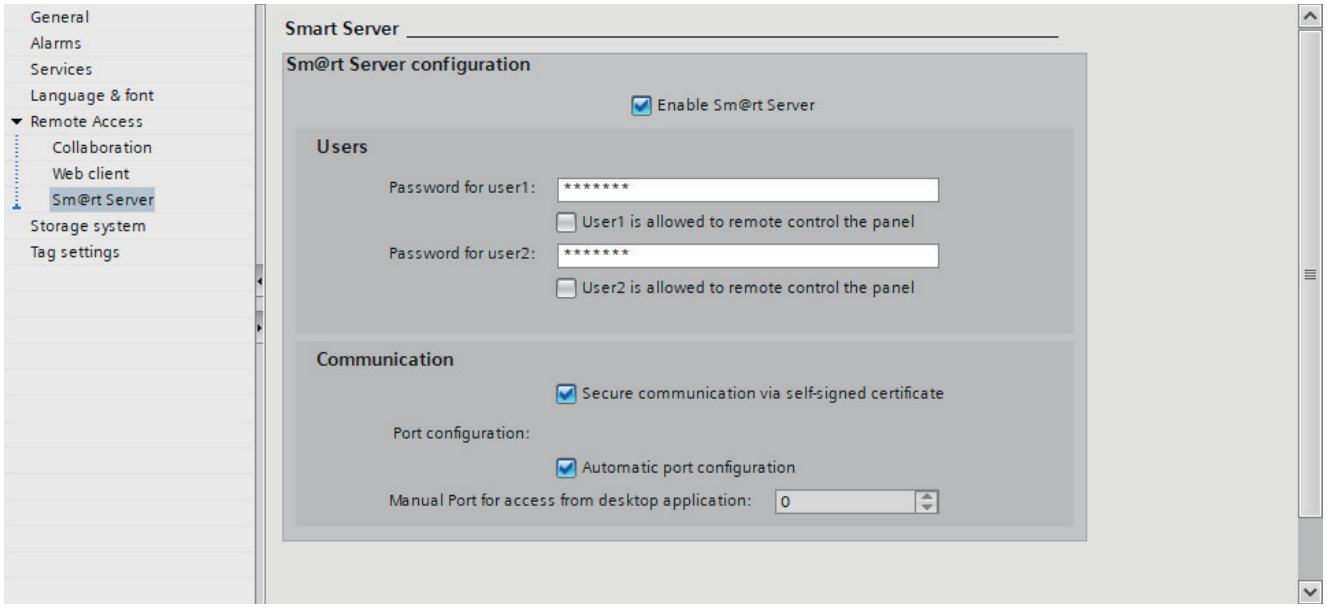
To configure the Smart Server, follow these steps:

1. Open the "Runtime settings" of the Unified Control Panels in the project tree.
2. In the "Runtime settings", expand the "Remote access" menu command.
3. Click "Smart Server".
4. Enable the "Enable Smart Server" setting in the "Smart Server Configuration" group.
5. Assign a password for "User1" and "User2" respectively.
   Note the Rules for passwords (Page 7608).
6. Activate "Secure communications via self-signed certificates".

   Note

   If "Secure communication using self-signed certificates" is not enabled, the communication is not encrypted.

7. If you do not want to use automatic port configuration, disable the option and assign a port manually.
8. Compile and download the project onto the Unified Comfort Panel.



18.4.5 Settings in the Control Panel of the Smart Server

The settings on the Control Panel of the Unified Comfort Panel regulate which remote operator is permitted to access the Smart Server application.

The options in the Control Panel are analogous to the runtime settings in the TIA Portal.

Note that the settings on the Unified Comfort Panel are overwritten when a project is downloaded from the TIA Portal.

Procedure

To configure the Smart Server in the Control Panel of the Unified Comfort Panel, follow these steps:

1. In the Control Panel of the Unified Control Panel, open the menu item "Network and Internet".
2. In the area "Remote access > Smart Server" enable the setting "Enable Smart Server".
3. Select one or more users for remote access.
4. Assign a password for each user.
   Note the Rules for passwords (Page 7608).
5. Activate "Secure communication via self-signed certificate".

   Note

   If "Secure communication via self-signed certificate" is not enabled, the communication is not encrypted.

6. If you do not want to use automatic port configuration, disable the option and assign a port manually.

18.4.6 Configuring the Smart Client application

18.4.6.1 Dialog "New SmartServer: Connection"

This dialog opens when you click the "SmartClient" button in the taskbar.

It is used to set the desired Smart Server and to select the connection method.

The following configuration options are available to you:

SmartServer

Enter the address of the server to which the connection is to be established. You can find the various options for entering the address under Remote control by means of the Smart Client application (Page 7613).

Connection profil

Select the type of connection to the Smart Server according to the network you are using.

Options

Opens the "Smart Client Options" dialog box with the technical settings for the Smart Client application.

18.4.6.2 "Options" dialog, "Connections" tab

The settings for the Smart Client application are specified in this dialog.

The following configuration options are available to you:

Format and encodings

Settings for compressing the screen data of the Smart Server.

- Use encoding
  Preassigned based on the selection under "Connection profile".
  Select the desired compression or "Raw" (no compression).
- Use 8-bit color
  Reduces the color depth at the client to 8 bits (256 colors). The data are then transferred faster. However, incorrect colors may result.
- Custom Compression level
  Allows individual customizing of the compression level in the "Level" input field:
  1 = least compression (faster); 9 = maximum compression (slower).
- Allow JPEG compression
  Allows the use of JPEG compression (involves losses).
  Enter the "Screen quality" in the input field underneath:
  1 = least compression (faster); 9 = maximum compression (slower).
- Allow CopyRect encoding
  Allows compression while using "similar rectangles".

Restrictions

- View only (inputs ingnored)
  Sets the view mode for this Smart Client irrespective of the settings on the Smart Server. This allows you to prevent unintended control operations.
- Disable clipboard transfer
  Turns off the clipboard.
  Applies only to the copying and pasting of texts.

Display

Settings for the screen display

- Scale by
  Zooms in or zooms out the desktop to be displayed.
- Full-screen Mode
  Displays the desktop to be shown in full-screen mode. If the display on the Smart Server is larger than the screen of the Smart Client, it is scrolled automatically by the mouse movement.

Mouse

Settings for the evaluation of mouse actions

- Emulate 3 Buttons (with 2-button click)
  Emulation of a three-button mouse by a two-button mouse.
- Swap mouse buttons 2 and 3
  Mouse buttons 2 and 3 are swapped.

Mouse cursor

Settings for the display of the cursor

Select the type of transfer of the mouse actions:

- Track remote cursor locally
  The information on the location of the cursor is transferred separately from the screen information. This speeds up the transfer of the cursor.
- Let remote server deal with mouse cursor
  Moves the Smart Server mouse pointer to the Smart Client mouse pointer. This allows more accurate cursor positioning.
- Don't show remote cursor
  The cursor at the Smart Server is not included in the transfer.

18.4.6.3 "Options" dialog, "Globals" tab

Technical settings for the Smart Client application are made in this dialog.

The following configuration options are available to you:

Interface options

- Show toolbars by default
  Shows the toolbar.
- Warn at switching to the full-screen mode
  Outputs a message before the full-screen mode is activated.

- Number of connections to remember
  The Smart Client creates a list of the recently used connections. This setting specifies the number of connections listed.
- Clear the list of saved connections
  The list is cleared.

Local cursor shape

Specifies the appearance of the local cursor. This makes it easier to differentiate between the local mouse pointer and the remote mouse pointer.

Logging

- Write log to a file
  Writes information to the logbook of the Smart Client application.
- Verbosity level

18.4.7 Remote control by means of the Smart Client application

Introduction

On the Smart Client, the Smart Client application provides the connection to the remote Unified Comfort Panel.

Requirement

- Both devices are connected with via a TCP/IP capable network.
- In the TIA Portal project of the Smart Server or in the Unified Comfort Panel, the setting "Enable Smart Server" is selected in the runtime settings under "Remote access > Smart Server".
  Note that the settings on the Unified Comfort Panel are overwritten when a project is downloaded from the TIA Portal.

Sequence

Remote monitoring or remote control is supported on the Smart Server.

Remote monitoring or remote control can be implemented on the Smart Client using the Smart Client application.

Remote control via the Smart Client application works as follows:

- Start the Smart Client application
- Establish connection
- Password input
- Operator control and monitoring on the Unified Comfort Panel

Install SmartClient application

The SmartClient application is executed via the "SmartClient.exe" file.

- If WinCC Runtime is installed on the SmartClient, the SmartClient application is also installed.
- If WinCC Runtime is not installed on the SmartClient, you have several options:
  - You copy the SmartClient application from the WinCC Runtime product DVD.
  - You copy the SmartClient application from the installation path from another PC.

Start the Smart Client application

- To connect to the remote Unified Comfort Panel, call the Smart Client application and enter the IP address of the Smart Server.
  - IP address or server name:port number
    - or -
  - IP address or server name:display number

  Example: "192.168.0.1::5800"

Other options to start the Smart Client application:

- Enter the name of the executable file and the IP address in the command line:
  `smartclient.exe 192.168.0.1`.
  The Logon dialog box appears.
  - or -
- Enter the name of the executable file, the IP address and the password in the command line:
  `smartclient.exe 192.168.0.1 /password <Password>`.

Password input

- Password input at the Smart Server
  Instead of the on-screen keyboard, the following message is displayed on the Smart Client when you enter the password directly at the Smart Server: "Remote access by Smart Options is in Progress. Please wait until the input of values has been ended." This measure prevents keyboard input for entering the password from being displayed on the Smart Client.
- Password input at the Smart Client
  The display of the screen keyboard on the Smart Server by actions on the Smart Client is suppressed. Use the local on-screen keyboard for entries at the Smart Client. The local on-screen keyboard on the Smart Client is automatically displayed. Close the on-screen keyboard manually. Select "Input > Hide Input Panel" to hide the local on-screen keyboard.

Note

The entries with full-screen keyboard are not protected on devices with a screen size of ≤ 6".

Entries in Control Panel Applets which do not use the full-screen keyboard are protected.

Note

Hidden password input is not supported by the on-screen keyboards of third-party products.

Note

It is not possible to enter special characters in combination with [AltGr].

Operation with the keyboard

For operator control via the keyboard, the following is available:

Keyboard shortcut	Function
<Alt+Ctrl+SHIFT+O>	Opens the "SmartClient options" dialog.
<Alt+Ctrl+SHIFT+F>	Switches over to full screen mode
<Alt+Ctrl+SHIFT+R>	Updates the display
<Alt+Ctrl+SHIFT+N>	Opens the "New SmartServer Connection" dialog
<Alt+Ctrl+SHIFT+S>	Save as
<Alt+Ctrl+SHIFT+T>	Displays and hides the toolbar

Result

The entire layout of the remote Unified Comfort Panel is shown in the application window. Depending on the configuration, you can specify monitoring only or operator control of all keys with the mouse.

18.4.8 Use and limitations of the Smart Server

Use restrictions

When using the Smart Server, observe the following notes:

- Smart Server and Smart Client
  - Use only simple projects.
  - Avoid photographs and color gradients in screens.
  - Avoid heavy background loads during operation, for example, those from user-defined functions or logs.
  - The maximum number of connected Smart Clients depends on the Unified Comfort Panel. For additional information, see the "Performance features" documentation.
  - To improve the performance of the Smart Server, you can disable the hardware acceleration of the graphics card.
  - For client access of a PC with touch screen to a SmartServer, the following applies to the touch operation of the SmartClient:
    Standard touch operation such as clicking or scrolling in lists is possible, but touch gestures and events such as "Press" and "Release" are not supported.
  - If you access a Unified Comfort Panel via the Smart Client, this leads to reduced performance on the HMI device.
- Access protection
  To protect access to an Unified Comfort Panel using different passwords, use the first password for protected access and the second password for unprotected access; for example, remote control with password and remote monitoring without password.
  Passwords must be assigned. It is not permitted to leave passwords blank.
- Port
  The connection to the web server is established via port 443 (HTTPS over SSL / TLS) or via port 80 (HTTP, unencrypted). For the web server to start without problems, make sure that port is not in use by any other application, such as the IIS World Wide Web Publishing Service.
- Timeout
  If the connection between the Smart Server and a Smart Client is interrupted, the server will register this disconnection only with a certain delay. The delay is based on the Windows standard configuration of TCP/IP Timeout.

Use-requirements in the company network

If the company network is protected by a Firewall, the system administrator must enable the corresponding port:

- The Smart Server is connected to the network via port 5900.

You change the port number in the Runtime settings under "Remote access > Smart Server" in the settings for "Communication" or in the same way in the Control Panel of the Unified Comfort Panel.

Options 19

19.1 WinCC Audit

19.1.1 Basics

19.1.1.1 GMP compliance

GMP-compliant projects with WinCC

Traceability and therefore the documentation of production data is becoming increasingly important in many sectors, for example

- Pharmaceutical industry
- Companies in the food and beverage industry or in the related mechanical engineering industry

Storage of production data in electronic form offers many advantages compared to paper documents, such as simple acquisition and logging of data.

Events that are relevant for monitoring and ensuring the correctness of the process occur during runtime. Although the data provides information about a specific action, it is complicated for the user to easily identify the relevant data in the data set, such as: Cause of the change in value, actions that led to the change, or additional details about the change itself (e.g. source, location, cause).

However, it is also important to ensure that data cannot be falsified and that it can be read at any time.

Therefore, sector-specific and cross-industry standards have been developed for the electronic documentation of production data.

The most important set of regulations is the FDA Guideline 21 CFR Part 11 for electronic data records and electronic signatures issued by the FDA, the US Food and Drug Administration. In addition, different EU regulations apply, for example, EU 178/2002, depending on the industry.

Requirements for production systems in these industries have been developed on the basis of 21 CFR Part 11 and the corresponding layout to comply with GMP (Good Manufacturing Practice). They are also required for other industries.

The following primary requirements are derived from these directives and rules:

- Creation of an Audit Trail or operating trace in runtime
  Based on this document, it is possible to trace the user who carried out an operator action on the machine at what time.
- Important process steps must also be assignable to a clear responsibility, for example, via an acknowledgment or a comment.

19.1.1.2 GMP-compliant configuration

Introduction

"Configuration conforms to GMP" means creating projects in accordance with "Good Manufacturing Practice". The requirements are set out in FDA rules "21 CFR Part 11". The FDA is the U.S. Food and Drug Administration. Eudralex Volume 4, Appendix 1, EMA regulation 178/2002 also applies. EMA is the European Medicines Agency.

GMP-compliant configuration means HMI devices have electronic production data documentation functionalities.

Note that the WinCC Audit option is currently only available for Unified SCADA.

GMP-relevant and Audit Trail

WinCC offers the "Audit" option for implementing GMP compliance. Using the Audit option, the "Configuration conforms to GMP" function can be enabled.

Enable the "Configuration conforms to GMP" function directly in the runtime settings of the HMI device. GMP relevant functionalities are then added to WinCC. These functionalities are:

- Option to label tags as "GMP relevant".
- Suggestions for the comment with typical reasons for changes of GMP-relevant tags can be pre-defined by selecting text lists.
- Automatic identification of significant changes in GMP-relevant tags
- Generation and storage of electronic records of the relevant changes - Audit Trail
- System function for recording relevant user actions - electronic recording
- Recording of manipulated log data with checksum
- Audit trail record for printing logged changes

Execution of or changes to labeled objects are saved in a special log, the "AuditTrail".

Licensing

To use the GMP relevant functionalities configured in WinCC in runtime, you need the following license:

- WinCC Audit for RT Unified

19.1.1.3 Audit option

Advanced functions

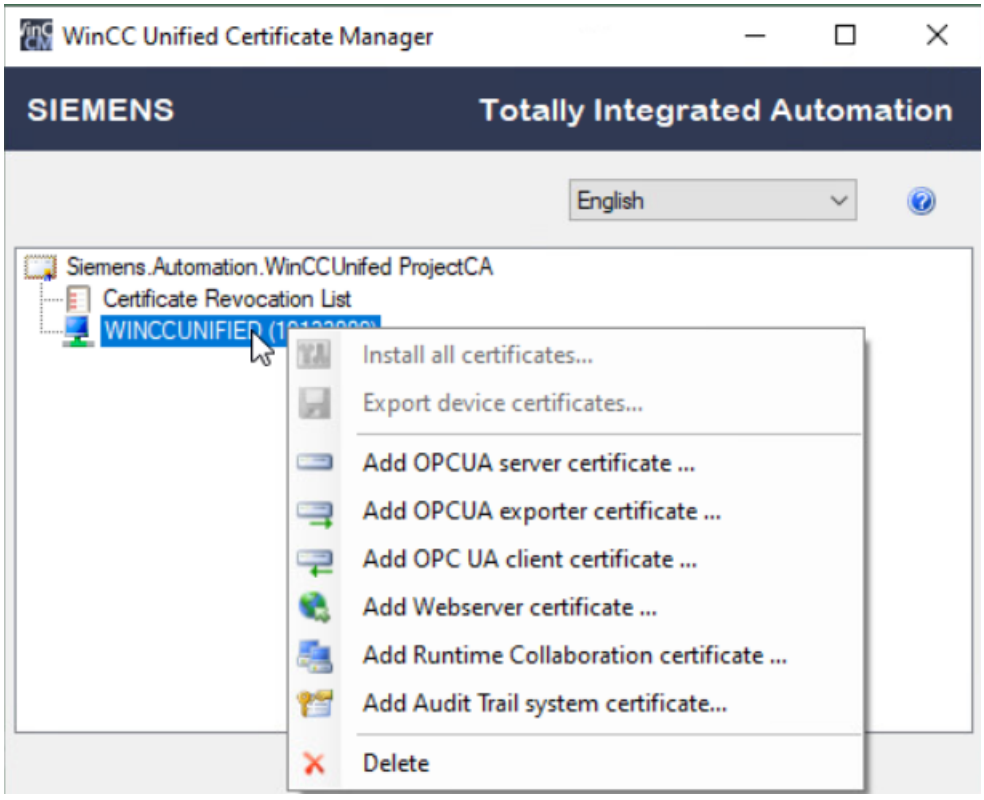
The Audit option adds functions to WinCC to ensure that your project is GMP compliant.

The following functionalities are added:

- Audit Trail
  For each HMI device, you can create one Audit Trail .
  Operator actions and system processes that are relevant for the FDA compliance of the process are recorded in an Audit Trail during runtime.
  - Actions by the system, such as starting up runtime or rejecting logon attempts.

Audit Trail certificates in Runtime

Audit Trail certificates are required for the HMI device. The certificates are used to check integrity and prevent tampering with the archive. To install the certificate on the HMI device, use the WinCC Unified Certificate Manager. Note that the maximum lifetime of a certificate is 150 months.



Note

Note that an error message appears in the alarm control without the certificate or with an expired certificate.

Extension of the WinCC engineering system

For HMI devices that support "Configuration conforms to GMP", the WinCC engineering system is extended to include the following configuration options when GMP is enabled:

- The Audit Trail entry is added to the "Logs" editor
- A "Good Manufacturing Practice Settings" entry is added to the "HMI tags" editor in the Inspector window of a "Properties > Properties" tag
- "InsertElectronicRecord" system function

See also

Configuring the "InsertElectronicRecord" system function (Page 7637)

19.1.1.4 Scope of logging

It is important to ensure that Audit-related processes are always logged in runtime in the Audit Trail in a project with the option "Audit". Logging of the Audit Trail depends on the device used.

You have two options for logging your data in WinCC Unified:

- File-based logging
  File-based logging allows you to log up to 5000 logging tags in an SQL Lite database.
  You do not need a license to log logging tags in WinCC Unified PC.
  You need a WinCC Unified Runtime (RT) license to log logging tags in WinCC Unified PC.
- Database-based logging
  Database-based logging allows you to log all logging tags up to the high limit in an MS SQL database.
  Database-based logging is only available for WinCC Unified PC, and you need a WinCC Unified Runtime (RT) license to log logging tags.
  Besides the functionality, database-based logging also includes an MS SQL server. Therefore, you need the "WinCC Unified Database Storage" license.

Scope of logging

The following Audit-relevant processes are logged depending on the configuration of the tags of the project:

- Value changes of GMP-relevant tags by the user
- "InsertElectronicRecord" system function
  You use the "InsertElectronicRecord" system function to record user actions that are not automatically recorded by the Audit Trail.
  You can configure this system function to screen calls, for example, or you configure function lists containing system functions that do not require acknowledgment.

19.1.1.5 Performance features of the GMP-compliant configuration

Supported HMI devices

Supported HMI devices

The qualification "GMP relevant configuration" can be configured for the following HMI devices:

- Unified PC
- Unified Comfort Panel

Restrictions

Restrictions

The following functions and configurations cannot be used simultaneously with the qualification "GMP relevant configuration":

- PN direct keys
- DP DirectKey
- Events of screen objects
  You can set important user actions as GMP-relevant in runtime, such as changing tag values. In this case, you may not assign any other events to this graphic object.
  When the event of a screen object is assigned actions which open a user dialog, you may not be able to execute these actions at other events.
- Controlling GMP-relevant tags using a slider
  The slider is not suitable for controlling GMP-relevant tags. Any operation of the slider will continuously change the tag value. If this is a GMP-relevant tag, a flood of entries is generated in the "AuditTrail".

19.1.2 Using the Audit trail

19.1.2.1 Enabling GMP compliant configuration

Introduction

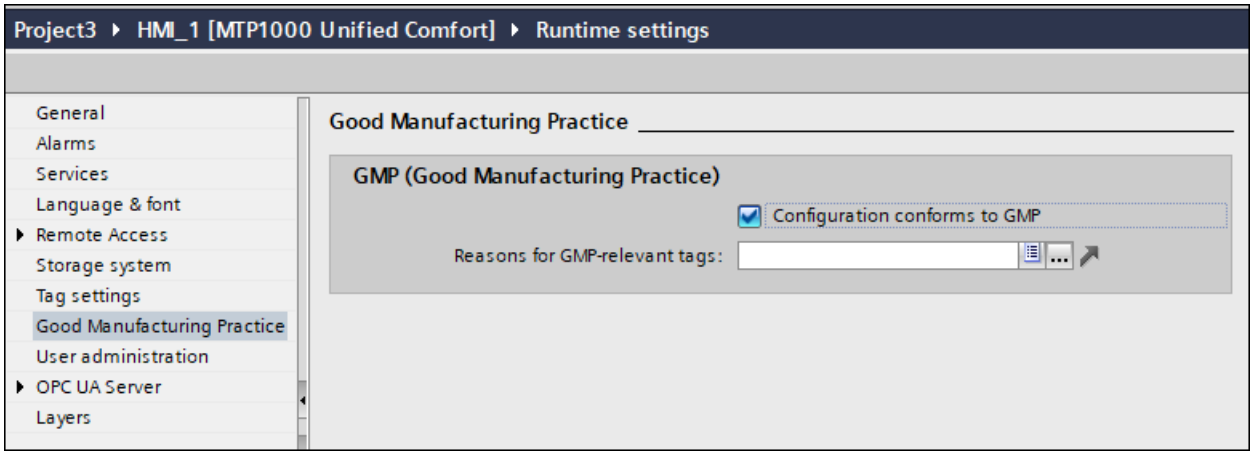
The function is made available to the Audit Trail by labeling it "Configuration conforms to GMP".

Requirements

- A project is created.
- A GMP compatible HMI device has been created.

Procedure

1. Click on the HMI device in the project tree.
2. Double-click on "Runtime settings" in the project tree. The editor opens.
3. Click on "Good Manufacturing Practice".
4. Select "Configuration conforms to GMP".



Result

The Audit option is now enabled for the HMI device.

The following functions can now be configured:

- Audit Trail log
  - For each HMI device, you can create one Audit Trail
- "InsertElectronicRecord" system function
- GMP-relevant tags
- Reasons for GMP-relevant tags (available text lists with pre-defined comments for acknowledgment in Runtime)
- GMP relevant recipes

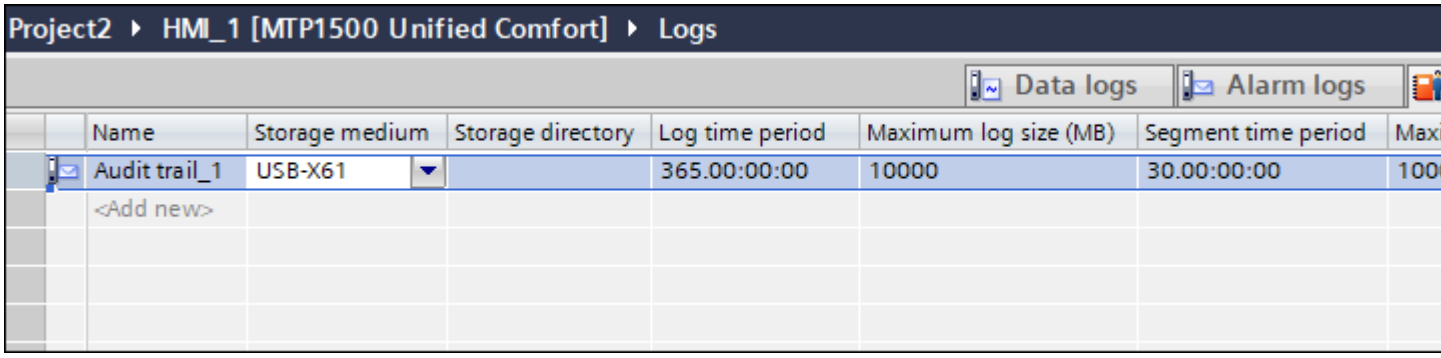
19.1.2.2 Creating an audit trail

Requirements

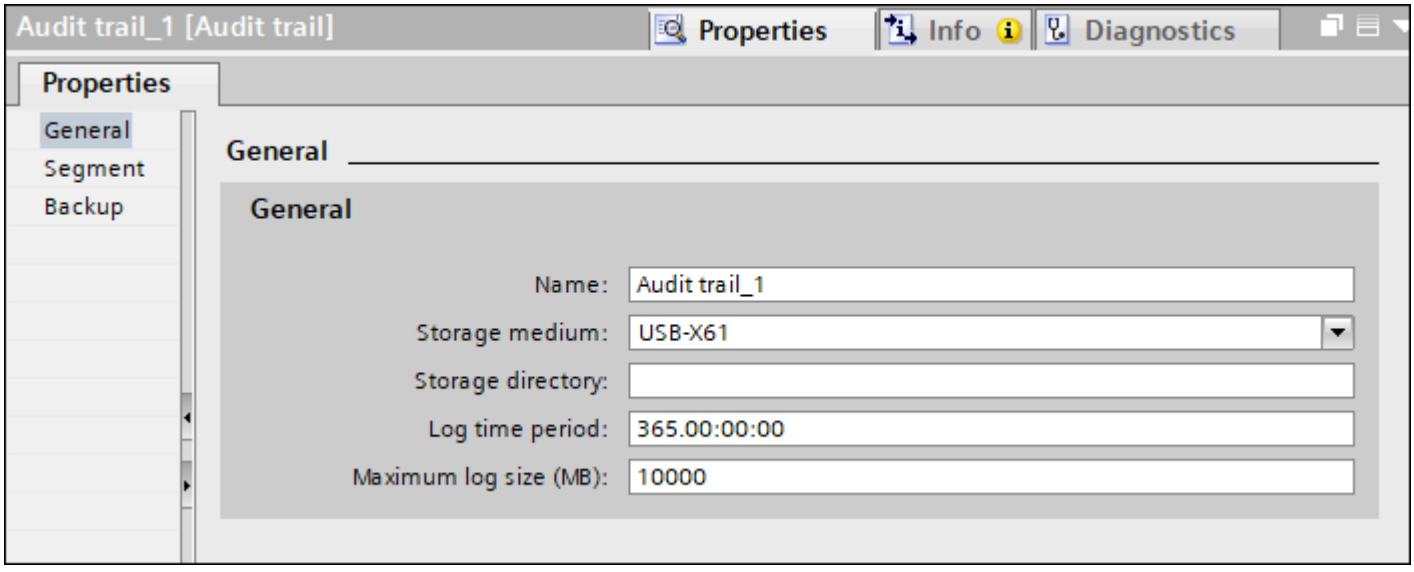
"Configuration conforms to GMP" has been selected on the HMI device. You can only create one Audit Trail per HMI device.

Procedure

1. Click on the HMI device in the project tree.
2. Double-click "Logs".
   The "Logs" editor will open.
3. Change to the "Audit Trail" tab.
   An Audit Trail has been created.



4. Set the parameters of the "AuditTrail" in the Inspector window under "Properties > Properties > General".



Storage medium and storage directory

The following settings are available for the storage medium and the storage directory:

- Default: You select the storage location that is defined in the WinCC Unified configuration on the runtime machine as storage directory.
- Local: Under storage directory, enter the path to the storage location. Make sure that the user has write permission.
- Project folder: As storage directory, you select the runtime folder to which the project data is copied after the download.

Log time period

The standard time period is 365 days. You can specify the log time period in the following format: Days.Hours:Minutes:Seconds.

Maximum log size

The standard log size is 10 GB. The value is entered in MB. When the maximum log size has been reached, the oldest entries are overwritten.

Log segments

The size of the log segments is specified either as a time period or a segment size. You specify the following under "Properties > Properties > Segment":

- Segment time period: The standard time period for logging a single segment is 30 days. You can specify the time period in the following format: Days.Hours:Minutes:Seconds.
- Maximum segment size: The standard segment size is 1 GB. The value is entered in MB.
- Segment start time: Specifies the start time of the log segment.

Backup

When the databases exist in the MSSQL format, you can create backups of the database under "Properties > Properties > Backup".

1. Under "Backup mode", select the "Path" setting.
2. Enter a storage location under "Backup path".

19.1.2.3 Audit Trail reports

Basics

Based on an Audit Trail report, it is possible to trace the operator who carried out operator actions at what time. The configuration engineer uses the WinCC Unfied Excel add-in to configure a report template with Audit Trail parameters that are relevant for quality assurance in the manufacturing process. You can print out the report either as an Excel file, a PDF file or send it via email.

General information on configuring report templates in the Excel add-in is available in Creating report templates for production protocols (Page 7655).

General functions on the configuration of report jobs in runtime are available in Working with production protocols in runtime (Page 7719).

Audit Trail parameters

The following table contains an overview of the potential values of the individual report columns:

Parameter	Description
Time stamp	Contains the time stamp at which the event occurred.
Object name	Contains the name of the object that triggered the change.
User	Contains the name of the logged-on user. When no user is logged on, the field remains empty.
Operator Station	Contains either the name of the PC, PLC or the IP address of the web client.
Old value	Contains the tag value before the change.
New value	Contains the tag value after the change.
Cause	Contains the user comment. Contains the confirmation of the desired state.
Event ID	Contains the internal identifier of the event.
Tracking ID	Contains the internal identifier to link the user action to the system response.
Provider type of the audit	Contains an identifier for the type of intervention: 2 - Task scheduler 6 - Operator action 11 - System response
Audit provider	Contains the name of the provider, for example, Scheduler, User Interface, Event Manager.
Type of operation	Contains an identifier for the change: 1 - New value 2 - Updated value 3 - Deleted value
Object reference	Contains an identifier of the triggering object. This parameter is reserved for internal purposes.
Integrity	Contains an identifier for proof that data was manipulated later.

Add Audit (Page 7424)

Adding or editing configurations for audit (Page 7434)

Add Audit

Introduction

To output the Runtime device Audit Trail in a report, add an Audit data source item to a report template.

You can find more information about the Audit option in WinCC Unified in the TIA Portal help.

Requirement

- The Audit option was activated in the engineering for the Runtime device.

- The "Audit" option is activated in the connection settings of the Excel add-in.
- The "WinCC Unified" tab is visible in Excel.
- A time series segment is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
   The list with the segments already created is loaded.
2. Select a time series segment.
   The segment is extended by the area for the data source items.
3. Click "+".
4. Select the "Audit" option.
5. Select the Audit Trail.
6. (Optional) To undo your selection, select the Audit Trail under "Selected data source items" and click "Delete".
7. Confirm with "OK".

Result

The Audit data source item is displayed below the segment.

If an Audit Trail is configured for the data source, the Audit data is inserted into the report when the Runtime data is read into Excel and when it is generated in Runtime:

- In the legend table: Identifier of the overall status of the Audit Trail for the queried time range in the "Audit Status" field

Value	Description
Green	No manipulations of the Audit Trail were found in the queried time range.
Red	Manipulations of the Audit Trail were found in the queried time range. Single or multiple entries have been deleted, added or changed.

Requirement: The "Audit status" option is activated on the segment under "Header properties".

Note

Overall status for check mode "None"

If the check mode "None" is set in the configuration of the audit data sources item, the "Audit status" field is always green.

- In the data table of the segment: Identifier of manipulations

Type of manipulation	Identifier in the data table
Value of entries changed	Directly at the entries
Entries added	
Entries deleted	The manipulated time range receives a start and end entry.

First, the data table shows the contents configured in the standard configuration for Audit. To output other contents, select or create a configuration.

Adding or editing configurations for audit

Introduction

Check mode

The check mode of the configuration of an audit data source item determines

- whether an integrity check is performed when the runtime data is read, and what is checked. You can output the overall result of the check in the table header row in the "Audit status" field.
- Which audit data records are provided in the data table.

Possible check modes:

"None"	Provides the data for all audit data records that fall within the requested time range. No integrity check is performed. Default setting
"Check only"	Checks all audit data records that fall within the requested time range without providing their data. It is tested whether data records have been manipulated, deleted or added.
"Check entries"	Checks the audit data records that fall within the requested time range and that have not been deleted from the audit trail or subsequently added, and provides their data. It is checked whether data records have been manipulated.
"Check all"	Checks all audit data records that fall within the requested time range and provides their data. It is tested whether data records were manipulated, deleted from the audit trail or subsequently added.

Filter type

An Audit data record consists of two entries:

- An entry for the user expectation
- An entry for the system response.

User expectation and system response may differ. In addition, there are cases in which only one of the two entries is created.

The filter type controls which data records and which entries are included in the report.

Possible filter types:

Filter type	**User expectation equals system response**	**User expectation does not equal system response**	**Data record entry for user expectation or system response is missing**
"Show all data in detail"	Both data record entries are inserted.		The existing data record entry is inserted.
"Show data and conformity errors"	The data record entry with the user expectation is inserted.	Both data record entries are inserted.	
"Show only data with conformity errors"	No data record entry inserted.		

Requirement

- The "WinCC Unified" tab is visible in Excel.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration".
3. Click "New Configuration > Audit configuration".
4. Enter the name of the configuration under "Name".
5. Select a check mode:

6. Determine which audit attributes are displayed. To do this, activate the options for the desired columns under "Columns".
7. Specify a filter type.
   Preset value: "Show data and conformity errors"
8. (Optional) To further filter the inserted content, define a filter query.
   The filter query can consist of up to two conditions. Follow these steps:
   - Under "Filter query", click "+" or "Add new condition row".
   - Select an Audit attribute, an operator and enter the value of the attribute.
   - Optional: Use "+" or "Add new condition row" to create further conditions and select whether the conditions are to be linked with a logical AND or OR.
9. Confirm your entries with "OK".

Editing a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration".
3. Click a configuration for Audit.
4. Edit the configuration settings. You have the same options as when creating the configuration.
5. Confirm your entries with "OK".

The changes are applied the next time you read in the Runtime data.

Examples of the configuration of the filter type

The following table contains examples of data records that were generated in Runtime through changes to tags monitored by Audit:

Data record ID	Tag name	Modified by	Old value	New value	Description
1A	Motor1_Speed	User1	0	10	An operator changes the speed of a motor in an I/O field of an HMI screen.
1B	Motor1_Speed	System	0	10	User expectation and system response are identical.
2A	ValvePercentile	User1	0	100	An operator opens a valve using a slider on an HMI screen. The valve has a physical blockage and cannot be opened. Therefore, no data record entry for the system response is generated.

Data record ID	Tag name	Modified by	Old value	New value	Description
3A	ValvePercen-tile	User1	0	99	A physical blockage has been removed and the operator repeats the entry. The valve reacts, but cannot be fully opened. User expectation and system response differ.
3B	ValvePercen-tile	System	0	49	
4B	Mo-tor2_Speed	System	0	20	An operator changed the speed of another motor. The resulting data record was manipulated, and the user expectation entry was deleted. There is only one entry for the system response.

The following table shows which data record entries are inserted into the data table depending on the filter type selected when generating the report:

Data record ID	Tag name	Modified by	Old value	New value
Filter type "Show all data in detail"				
1A	Motor1_Speed	User1	0	10
1B	Motor1_Speed	System	0	10
2A	ValvePercentile	User1	0	100
3A	ValvePercentile	User1	0	99
3B	ValvePercentile	System	0	49
4B	Motor2_Speed	System	0	20
Filter type "Show data and conformity errors"				
1A	Motor1_Speed	User1	0	10
2A	ValvePercentile	User1	0	100
3A	ValvePercentile	User1	0	99
3B	ValvePercentile	System	0	49
4B	Motor2_Speed	System	0	20
Filter type "Show only data with conformity errors"				
2A	ValvePercentile	User1	0	100
3A	ValvePercentile	User1	0	99
3B	ValvePercentile	System	0	49
4B	Motor2_Speed	System	0	20

19.1.2.4 Audit trail logging concept

Format

Audit Trail format

On an HMI device with "Configuration conforms to GMP", all events that are relevant to the Audit are recorded in runtime in the Audit Trail. You have several format options.

Selection is dependent on the display program and the runtime language used:

- RDB file
  Data is saved with quick access in a proprietary database.
  If you require maximum read performance in Runtime, use the "RDB file" storage location.
- csv file
  To view and evaluate a csv file, use Microsoft Excel or similar on your PC.

  Note

  Double quotation marks or several characters are not permitted as list separators for the format "File - csv (ASCII)". You can find the settings for list separators under "Start > Settings > Control Panel > Regional and Language Options".

- TXT file
  This file format supports all characters that can be used in WinCC. For editing, you will need software that can save files in Unicode, such as Notepad.

  Note

  Use "File - TXT (Unicode)" to log Asian languages.

Audit Trail with checksum

Audit Trail with checksum is automatically generated in the database that is based on the user certificate. The certificates are created with the WinCC Certificate Manager Tool. You can find additional information in the Runtime online help in the Certificate Manager section.

Storage location and medium

Storage location and medium

Depending on the hardware configuration of the HMI device, the data may be logged locally (on the hard disk of a PC or on the storage card of a panel) or, if present, on a network drive.

Note

Logging on network drives

We do not recommend that you log Audit Trails directly on a network drive. Power supply can be interrupted at any time. This means there is no guarantee for a reliable operation of logs and Audit Trails.

We recommend you save the logs on your local hard drive, or on a storage medium of the HMI device. Use the system function "ArchiveLogFile" to save the logs long-term on a network drive.

"Configuration conforms to GMP" can only be fully operated in runtime as long as Audit-relevant user actions can be saved in the Audit Trail. It is important to ensure that sufficient memory space is available for the Audit Trail and that the connection to the storage location of the Audit Trail is not interrupted.

Error-handling with insufficient free storage space

If there is insufficient storage space, your project can be configured so that the administrator has an option of continuing the process without logging in the Audit Trail (forcing).

Error-handling if there is no storage medium or the connection to the server is interrupted

If the storage space for the Audit Trail is insufficient, for example, if there is no storage medium, all Audit-relevant user actions are blocked.

The block is canceled as soon as the storage location for the Audit Trail can be reached again. The block can be skipped by "forcing".

Error-handling with long-term logging

If the Audit Trail must be moved to a server for long-term logging and the connection to the server is interrupted at this time, the following error-handling is required:

The system closes the Audit Trail and renames it. The system attempts to send the renamed Audit Trail to the server again in the background.

If disruption in the connection to the server persists, you receive a system alarm telling you that the connection is down. Then the system attempts to send the renamed Audit Trail every 300 seconds.

The attempt to transmit the data is repeated until successfully completed. The data is also transmitted after a restart of the HMI device.

Protection mechanisms

Protective mechanisms to prevent changes to Audit Trail data

The Audit Trail data are protected against deliberate or accidental changes:

- The directory in which the Audit Trail is saved can only be accessed with special rights.
- The Audit Trail files are write-protected.
- In addition, electronic records that have been removed or added in a certain time segment are identified.
- Each data record contains a checksum that can be used to detect a change of its contents. The checksum is generated based on a certificate. This checksum also ensures that the number of lines has not changed in the Audit Trail file.

Use the "HmiCheckLogIntegrity" tool, included in the Audit option, to check whether an Audit Trail has been changed:

Upgrading WinCC

Upgrading WinCC

Before you update WinCC with a Service Pack or a new version, you will have to exit and save the Audit Trail or the logs with checksum. After WinCC is updated, the audit trail or logs with checksum will be continued with new files.

Make sure that the logs are started at a defined state with the new version.

Audit trail behavior in runtime

Effects in runtime

The configuration in Audit Trail has the following effects in runtime, depending on the configuration:

- Audit-relevant user actions (such as tag changes) are recorded in an Audit Trail.
- For GMP-relevant tags, the system automatically generates an electronic record as an action requested by the user (requested action) and an electronic record of the system reaction (performed action).
- "Enable logging at runtime start" check box enabled:
  The Audit Trail is started with runtime.
- "Forcing" group, "Allowed if storage space has been exhausted" check box enabled:
  A user with administrator rights can use "forcing" to run operations on the plant even though the Audit Trail can no longer be logged because of storage space limitations. Interrupting the Audit Trail prevents the process from being stopped.
  If the check box "Signing may be bypassed" is enabled, the administrator is not required to input electronic signatures, acknowledgments or comments for operator actions that would normally require signing, acknowledgment or comment.
- Depending on the configuration, the texts can be selected from a pre-defined text list for acknowledgment in Runtime.
- If the storage space available for the Audit Trail is less than the configured "Free storage space limit in MB", the function list configured for the "Low free space" event will be processed.
- If there is insufficient storage space for the Audit Trail because of hardware limits, the function list configured for the "Free space critically low" event will be processed.

19.1.3 Configuring audit functions

19.1.3.1 Logging tag value changes

GMP-relevant tags

GMP-relevant tags

To log changes to the tag value "Good Manufacturing Practice" (GMP), mark a tag as GMP relevant. Special consideration should be given to the following:

- Array tags: When you mark an array variable as GMP relevant, all elements are automatically labeled as GMP relevant. You cannot change the setting of the individual elements.
- User data types: When you mark a user data type as GMP relevant, all elements are automatically labeled as GMP relevant. You cannot change the setting of the individual elements.
- System tags: System tags cannot be marked as GMP relevant.

Changes to tag values

When a tag is marked as GMP relevant, changes to the tag value are logged in an Audit Trail.

- Value changes by a user are logged in the Audit Trail.
- Value changes caused by a system function that is configured to an event are logged when the system function is triggered by a direct user action.
- Value changes that are made by the PLC or a system function are not logged in the Audit Trail.

Effects in runtime

The configuration has the following effects in runtime depending on the properties of the GMP-relevant tags:

- If the user changes the value of a GMP-relevant tag in runtime, the value change is entered in the Audit Trail.
- Acknowledgment
  If "Acknowledgment" is specified as the "Type of confirmation", the user must acknowledge a value change of this tag. Otherwise, the value change is rejected.
  The acknowledgment is logged in the Audit Trail.
- Comment
  If the "Comment required" setting is selected in addition to the acknowledgment, the user must acknowledge and comment a value change of this tag. Otherwise, the value change is rejected. The user can enter the comment via a free text or via the pre-defined text list.
  The acknowledgment and the entered comment are logged in the Audit Trail.

Logging tag value changes

Requirement

- "Configuration conforms to GMP" has been activated in the Runtime settings.

Procedure

1. Open the HMI tags editor and select the tag for which you want to make GMP settings.
2. Click "GMP relevant" under "Properties > Properties > "GMP" in the Inspector window.

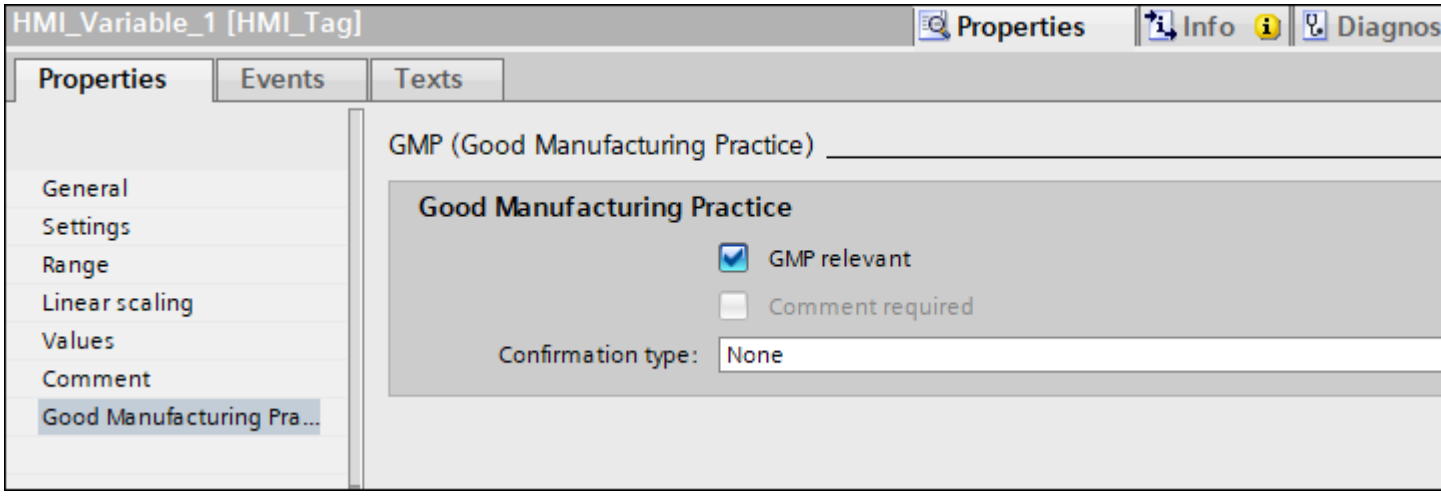

Figure 19-1 Marking a tag as GMP relevant

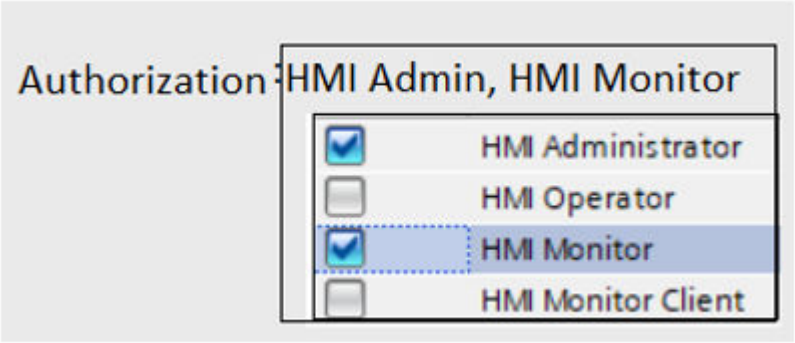
3. Specify how the user must confirm a value change in the "Confirmation type" selection field:
   - "None"
     If the value change is to be logged in the Audit Trail without user confirmation.
   - "Acknowledgment"
     If user acknowledgement of the value change is required.
4. Select the "Comment required" check box if the user is required to also enter a comment. This check box is only selected when "Acknowledgment" is specified under "Type of confirmation".

Confirmation type "Electronic signature"

If you have selected the electronic signature as the confirmation type, a drop-down list with the HMI roles is displayed.

Select which of the roles can confirm a value change.



Specifying comments via text lists

To keep the comments uniform, you can use text lists.

1. Create a text list with texts that can be selected for the comment.
2. In the runtime settings of the HMI device, select the text list in "Reasons for GMP-relevant tag".

19.1.3.2 Logging user actions

User actions with GMP-compliant configuration

Introduction

In a GMP-compliant configuration, user actions and system operations in runtime which are relevant for the quality of the process are recorded in an Audit Trail.

For example, a user logon to the system or the change of a tag value are saved in the log.

In runtime, user actions are saved in an Audit Trail under the following conditions:

- "Configuration conforms to GMP" has been enabled
- A user is logged on to the system

Logging modes

Configuration-dependent logging

The following processes are logged depending on the configuration of the tags of the project:

- Value changes of GMP-relevant tags by the user
  In addition to logging user actions, you can configure tags to require users to confirm or acknowledge specific actions and enter a comment on the change.

Manual logging by means of the "InsertElectronicRecord" system function

This system function is used to log actions in the Audit Trail that are not automatically logged in the Audit Trail.

Configuring the "InsertElectronicRecord" system function

Introduction

This system function is used to log user actions that are not entered automatically in the Audit Trail. Moreover, you can use this system and script function to request the user to enter an acknowledgment or a comment for the action.

You can configure this function even if the Unified Scada device is not configured as being GMP-compliant. However, current archiving in Runtime takes place only if the device is configured as GMP-compliant.

This function can be configured for screen objects, schedulers, global script. At present, this function is not available for faceplates.

In this example, the system function is assigned to a button. Every time the user operates this button, this action is logged in the Audit Trail.

Requirements

- "Configuration conforms to GMP" has been enabled.

Procedure

1. Click on a button in a screen.
2. Click on "Events" in the Inspector window.
3. In the function list, configure the "InsertElectronicRecord" system function to the "Click" event.

System function parameters

Parameter	Description	Type
Name	Specifies the name of the object.	String, HMI_tag, Screen object
Category	Specifies the name of the tag.	String, HMI_tag, Screen object
Operation type	Specifies the type of change.	1: New value 2: Modified value 3: Deleted value
Old value	Value before the change	Integer, Double, Bool, String, Color, HMI_tag, Screen object
New value	Value after the change	Integer, Double, Bool, String, Color, HMI_tag, Screen object

Parameter	Description	Type
Confirmation type	Specifies whether an acknowledgment is requested.	Specifies how the action must be confirmed. 0 = (None): No confirmation required, an entry is created in the Audit Trail 1 = (Acknowledgement): Acknowledgment, the user must acknowledge the action; an entry is created in the Audit Trail 2 = (Digital Signature): Electronic signature; a dialog window opens in which the user must enter the electronic signature - an entry is created in the Audit Trail
Reason (optional)	Is not supported	

Result

When a user operates the screen object in Runtime and triggers the event, the tag value is changed. An entry is created in the Audit Trail at the same time; depending on the parameters "Confirmation type" and "Reason", the entry is an acknowledgment and a comment.

GMP-compliant user administration

Central user management

Use the central user management to manage users and user groups centrally for multiple applications or HMI devices.

19.1.3.3 Recording system functions

Introduction

If system functions are triggered in runtime, this is recorded in the Audit Trail for some system functions. If specific system functions are used on a GMP-relevant object, the user must confirm the triggering.

Some system functions are not supported when using Audit. If you use these system functions in your project, you are solely responsible for them.

The following table shows which system functions are Audit-relevant and whether the user's signature is required:

System functions and Audit

Function (call in script)	Effect of /Audit
InsertElectronicRecord	Entered in Audit Trail
SetTagValue	Entered in Audit Trail
IncreaseTag	Entered in Audit Trail
DecreaseTag	Entered in Audit Trail

Function (call in script)	Effect of /Audit
ModifyBits	
SetBitInTag (SetBitInTag)	Entered in Audit Trail if the tag is GMP relevant Confirmation is dependent on tag configuration
ResetBitInTag (ResetBitInTag)	Entered in Audit Trail if the tag is GMP relevant Confirmation is dependent on tag configuration
InvertBitInTag (InvertBitInTag)	Entered in Audit Trail if the tag is GMP relevant Confirmation is dependent on tag configuration
SetBit (SetBit)	Entered in Audit Trail if the tag is GMP relevant Confirmation is dependent on tag configuration
ResetBit (ResetBit)	Entered in Audit Trail if the tag is GMP relevant Confirmation is dependent on tag configuration
InvertBit (InvertBit)	Entered in Audit Trail if the tag is GMP relevant Do not use the system function for tags that require acknowledgment or comment.
SetBitWhileKeyPressed (---)	Entered in Audit Trail if the tag is GMP relevant Confirmation is dependent on tag configuration
SetDataRecordToPLC (SetDataRecordToPLC)	Entered in Audit Trail if the recipe is GMP relevant Confirmation is dependent on recipe configuration
GetDataRecordTagsFromPLC (GetDataRecordFromPLC)	Entered in Audit Trail if the recipe is GMP relevant
ImportDataRecords (ImportDataRecords)	Entered in Audit Trail if the recipe is GMP relevant
ImportDataRecordsWithChecksum (ImportDataRecordsWithChecksum)	Entered in Audit Trail if the recipe is GMP relevant
ExportDataRecords (ExportDataRecords)	---
ExportDataRecordsWithChecksum (ExportDataRecordsWithChecksum)	---
LoadDataRecord (LoadDataRecord)	Entered in Audit Trail if the recipe is GMP relevant Confirmation is dependent on recipe configuration

Function (call in script)	Effect of /Audit
SaveDataRecord (SaveDataRecord)	Entered in Audit Trail if the recipe is GMP relevant Confirmation is dependent on recipe configuration
SetDataRecordTagsToPLC (SetDataRecordTagsToPLC)	Entered in Audit Trail if the recipe is GMP relevant Confirmation is dependent on recipe configuration
GetDataRecordTagsFromPLC (GetDataRecordTagsFromPLC)	Entered in Audit Trail if the recipe is GMP relevant
SetRecipeTags (SetRecipeTags)	Entered in Audit Trail if the recipe is GMP relevant
GetDataRecordName (GetDataRecordName)	---
ClearDataRecordMemory (ClearDataRecordMemory)	Not supported
ClearDataRecord (ClearDataRecord)	Entered in Audit Trail if the recipe is GMP relevant
PrintScreen (PrintScreen)	---
PrintReport (PrintReport)	---
RecipeViewSaveDataRecord (---)	Entered in Audit Trail if the recipe is GMP relevant Confirmation is dependent on recipe configuration
RecipeViewSaveAsDataRecord (---)	Entered in Audit Trail if the recipe is GMP relevant Confirmation is dependent on recipe configuration
RecipeViewNewDataRecord (---)	---
RecipeViewClearDataRecord (---)	Entered in Audit Trail if the recipe is GMP relevant
RecipeViewGetDataRecordFromPLC (---)	Entered in Audit Trail if the recipe is GMP relevant
RecipeViewSetDataRecordToPLC (---)	Entered in Audit Trail if the recipe is GMP relevant Confirmation is dependent on recipe configuration
RecipeViewSynchronizeDataRecordWithTags (---)	Entered in Audit Trail if the recipe is GMP relevant Confirmation is dependent on recipe configuration
RecipeViewRenameDataRecord (---)	Entered in Audit Trail if the recipe is GMP relevant
RecipeViewBack (---)	---
RecipeViewOpen (---)	---
RecipeViewMenu (---)	---
TrendViewScrollForward (---)	---
TrendViewScrollBack (---)	---
TrendViewExtend (---)	---

Function (call in script)	Effect of /Audit
TrendViewCompress (---)	---
TrendViewBackToBeginning (---)	---
TrendViewStartStop (---)	---
TrendViewSetRulerMode (---)	---
TrendViewBackToBeginning (---)	---
StatusForceGetValues (---)	Not supported
StatusForceSetValues (---)	Not supported
AlarmViewAcknowledgeAlarm (---)	Entered in
AlarmViewEditAlarm (---)	---
AlarmViewShowOperatorNotes (---)	---
HTMLBrowserBack (---)	Not supported
HTMLBrowserForward (---)	Not supported
HTMLBrowserRefresh (---)	Not supported
HTMLBrowserStop (---)	Not supported
ScreenObjectCursorUp (---)	---
ScreenObjectCursorDown (---)	---
ScreenObjectPageUp (---)	---
ScreenObjectPageDown (---)	---
PressButton (---)	---
ReleaseButton (---)	---
SmartClientViewConnect (---)	Not supported
SmartClientViewDisconnect (---)	Not supported
SmartClientViewReadOnlyOn (---)	Not supported
SmartClientViewReadOnlyOff (---)	Not supported
SmartClientViewRefresh (---)	Not supported
SmartClientViewLeave (---)	Not supported
ShowAlarmWindow (ShowAlarmWindow)	---
ClearAlarmBuffer (ClearAlarmBuffer)	---
ShowSystemAlarm (ShowSystemAlarm)	---
SetAlarmReportMode (SetAlarmReportMode)	---
Logoff (Logoff)	Entered in Audit Trail
GetPassword (GetPassword)	---
GetGroupNumber (GetGroupNumber)	---
ExportImportUserAdministration (ExportImportUserAdministration)	Import of user administration is entered in Audit Trail Export is not entered in Audit Trail
Logon (Logon)	Entered in Audit Trail
GetUserName (GetUserName)	---
TraceUserChange (---)	---
ShowLogOnDialog (---)	---

Function (call in script)	Effect of /Audit
LinearScaling (LinearScaling)	Entered in Audit Trail if the tag is GMP relevant Confirmation is dependent on tag configuration
InverseLinearScaling (InverseLinearScaling)	Entered in Audit Trail if the tag is GMP relevant Confirmation is dependent on tag configuration
IncreaseFocusedValue (---)	---
DecreaseFocusedValue (---)	---
OpenCommandPrompt (OpenCommandPrompt)	Not supported
OpenControlPanel (OpenControlPanel)	Not supported
ActivateCleanScreen (---)	---
AdjustContrast (---)	---

SetConnectionMode (SetConnectionMode)	Entered in Audit Trail
SetScreenKeyboardMode (SetScreenKeyboardMode)	---
ChangeConnection (ChangeConnection)	Not supported
SetLanguage (SetLanguage)	---
SetWebAccess (---)	Not supported
StartProgram (StartProgram)	Not supported
ShowSoftwareVersion (ShowSoftwareVersion)	---
SimulateTag (---)	Not supported
StopRuntime (StopRuntime)	Entered in Audit Trail
ControlWebServer (ControlWebServer)	Not supported
ControlSmartServer (ControlSmartServer)	Not supported
OpenInternetExplorer (OpenInternetExplorer)	---
SendEMail (SendEMail)	---
UpdateTag (---)	---
ClearAlarmBufferProTool (ClearAlarmBufferProtoolLegacy)	Not supported

Function (call in script)	Effect of /Audit
Encoding(Encode)	Entered in Audit Trail if the tag is GMP relevant Confirmation is dependent on tag configuration
EncodeEx(Encode)	Entered in Audit Trail if the tag is GMP relevant Confirmation is dependent on tag configuration

19.1.3.4 Standard entries in the Audit Trail

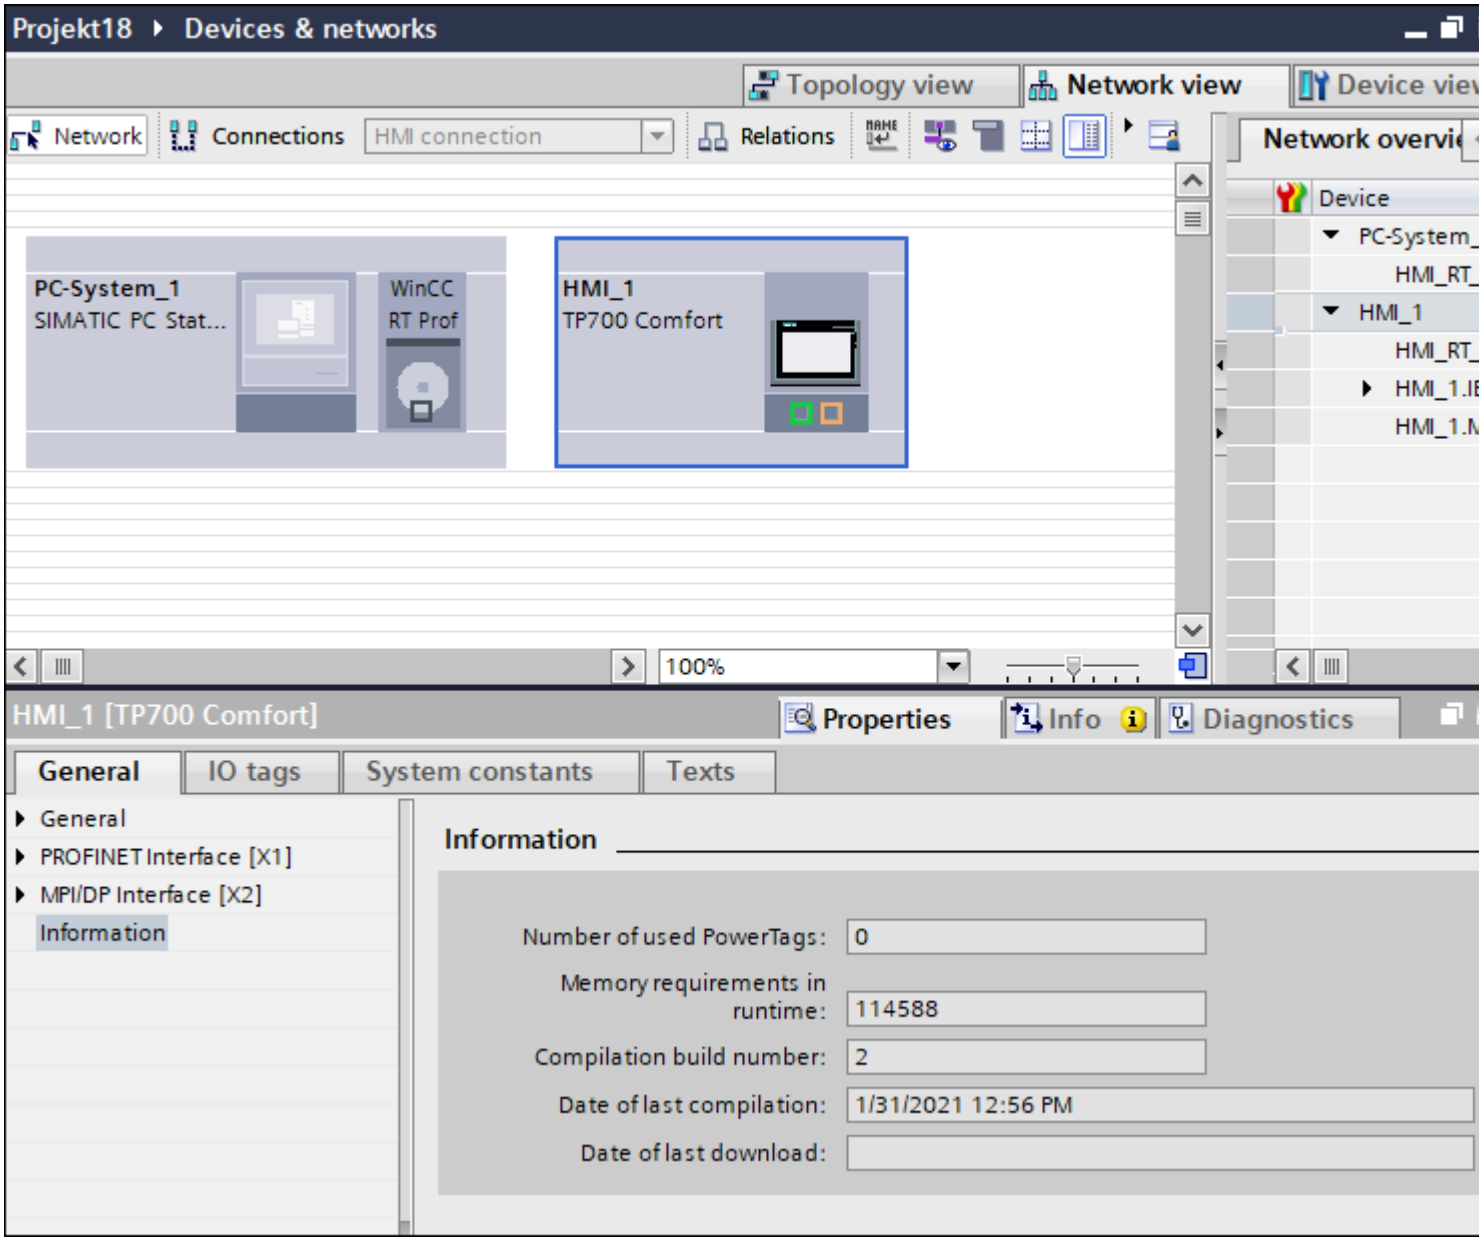
General entries in the Audit Trail

Individual operator actions are overwritten during logging. The following table shows examples of such entries:

Log entry	Description
Change of the tag value 'HMI_Tag_1' from '0' to'55'	Changing the value of a tag
User logged off.	Logging out a user.
Shutting down application.	Exiting the program.
Runtime start of WinCC Runtime Advanced	Starting WinCC Runtime Advanced
'Project.HMI_1 - 0' Build 2.	Information on the project, the device and the current version number

Version number of the device

The version number is incremented with each compilation of the device. You can find the version number in the Inspector window under "Properties > Properties > Information".



19.2 Creating production reports

19.2.1 Basics

19.2.1.1 Introduction

Note

Restriction for Unified Comfort Panel

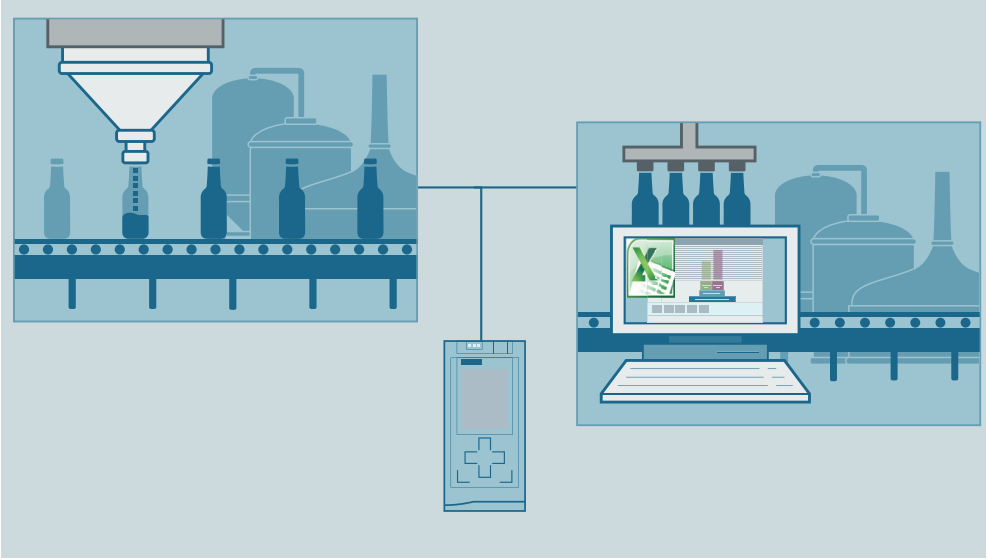
Contexts are not supported in V17 for Unified Comfort Panel. This option is not available in a report template with a Unified Comfort Panel as data source. When you generate a report on a Unified Comfort Panel whose report template uses this option, error entries are generated in the "ErrorLog" worksheet of the report.

Introduction

With WinCC Unified Reporting, you can generate tabular production reports in Runtime for the following project data:

- Logging tags and tags
- Log alarms
  Log the alarm properties of the recorded alarms and statistical calculations for display duration and frequency of the recorded alarms.
- Contexts:
  Log which contexts were running during a specific period or which project data occurred during the runtime of a specific context.
  - User-defined contexts:
    These contexts are created and executed by a program created with the ODK API.
  - System-generated contexts
    When the Performance Insight and Calendar option packages are installed, these contexts are executed by the system during Runtime.
- Audit Trail of the Runtime device
- If Plant Intelligence options are installed, you can use the WinCC Unified Local Reporting option to generate production reports for additional project data.
  You can find more information in the Help for the respective Plant Intelligence option.

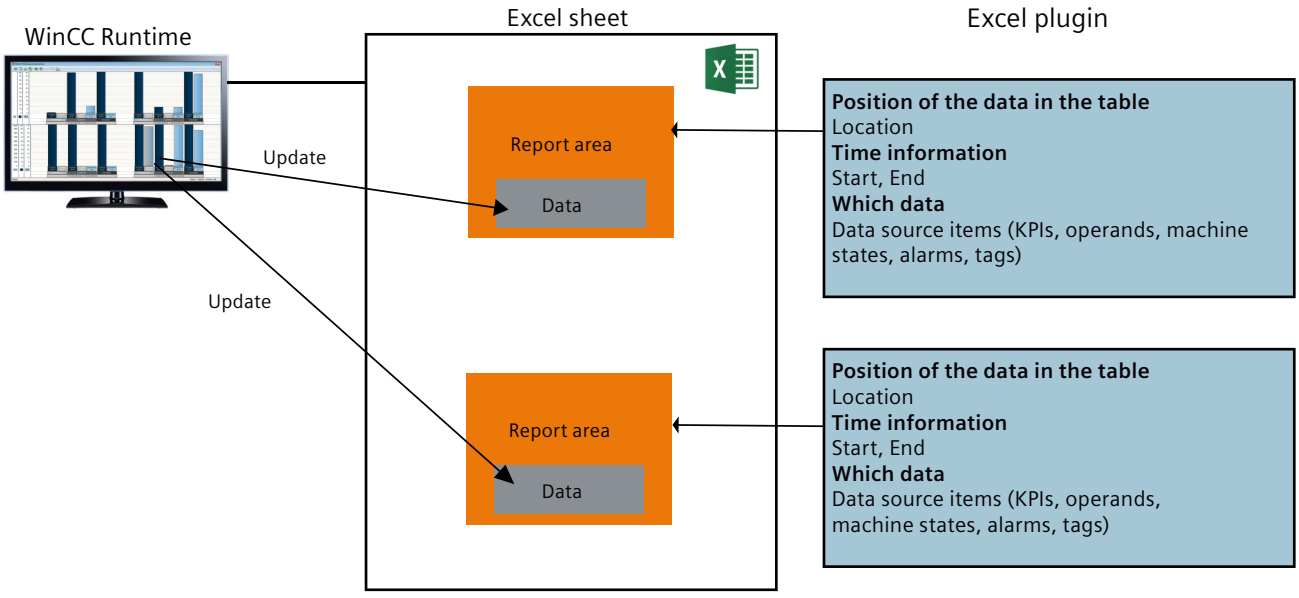
The production reports can be generated as XLSX file or PDF file and sent automatically as an e-mail to a specified group of recipients. For example, you can generate an XLSX report that outputs all alarms occurring in a production line. You then distribute or archive the report for analysis purposes.



Functional scope in the add-in

You create the report templates in an Excel add-in. For this purpose, Reporting offers the following functions in the add-in:

- Selecting a data source:
  - Online: A connection to a Runtime server on which a Runtime project is running.
  - Offline: A configuration file that contains the data of a Runtime project
- Definition of single value segments and time series segments
- Selection of the data source items of the segments
  Possible data source items:
  - Logging tags and tags
  - Log alarms
  - Contexts
- Definition of the report period (absolute or relative)
- Creation of type-specific data source item configurations
- Execution of individual segments or all segments for test purposes



Functional scope in Runtime

In the "Reports" control in Runtime, you configure report jobs that use the report templates defined in the Excel add-in. To do so, Reporting offers the following functions in Runtime:

- Maintenance of the global email settings (contact data and SMTP server configuration)
- Maintenance of job parameters, especially import and export of report templates
- Creating new report jobs and managing existing report jobs
- Overview of the generated reports
- Download or deletion of the reports

19.2.1.2 Basics of Reporting

Report templates

A *report template* is an Excel file (.xslx) that was created with the WinCC Unified Excel add-in. The report template has access to the data of the data source with which the add-in is connected.

For each report template, you define which segments are contained in the reports using the template and which data source items are evaluated by the segments.

After you have imported report templates into the "Reports" control in Runtime, you can select them for configuring report jobs.

Data sources

The *data source* is the source from which you select data source items when you configure the report template.

The following connection modes and data sources are available:

- Connection mode: Online
  The data source is the project that is running on the Runtime server to which the add-in is connected.
- Connection mode: Offline
  Data source is a configuration file. You generate the configuration file by exporting the data source items of the project to a file in the "Reports" control in Runtime. You can use this file to create additional report templates without connecting to a runtime server.

Options and data source items

Options control the types of data source items to which the report template has access.

Data source items are the specific objects whose data is read from the Runtime project during report generation.

The following options and types of data source items are available in Reporting, depending on the installed software:

Software	Option	Types of data source items
WinCC Unified basic installation	Alarms	Logging alarms Alarm statistics for logging alarms
WinCC Unified basic installation	Logging tag	Logging tags
WinCC Unified basic installation	Tag	Tags
WinCC Unified basic installation	User-defined column	User-defined texts or Excel formulas
WinCC Unified basic installation	Context	User-defined contexts Not available for Unified Comfort Panel
WinCC Unified basic installation	Audit	Audit
Performance Insight option package	Performance Insight	Local KPIs and operands of the PI option Performance Insight: • KPIs • Logged KPIs • Operands (counters and numerical operands) • Machine states • System-generated contexts
Line Coordination option package	Line Coordination	Jobs
Calendar option package	Context	System-generated contexts

Report jobs and job parameters

A *report job* is a job for generating reports in Runtime. A new report is generated each time the report job is performed.

The *job parameters* of the report order determine the details of its execution, such as which trigger it has, which report template it uses and the format of the report.

Report jobs are executed automatically when their trigger event occurs or manually by the user.

Reports

A *report* (production report) is an XLSX file or PDF file that is generated when a report job is executed in Runtime. The data source items from the Runtime project defined in the report template are read during generation, and their data are imported into a table in the report.

Using general Excel functions

In addition to the specific add-in functions, you also have access to the standard Excel functions in a report template. These include:

- Layout functions
- Functions for graphical preparation or analysis of the data imported from Runtime, such as charts, pivot tables and formulas

See also Tips on design and layout (Page 7717).

19.2.1.3 General requirements and restrictions

Installing the Excel add-in

The installation of the Reporting add-in on a computer requires that the operating system and the local MS Excel installation are regularly updated.

If there are problems with the installation, check the version of the local MS Excel installation. Lengthy maintenance intervals between the operating system and Excel can cause problems during installation of the add-in.

Update the operating system and the Excel version if necessary.

To install the add-in with a local Excel installation, MS Excel with build 16.0.6769 or higher is required.

Note

Note the Microsoft upgrade restrictions

If you have an Excel installation that cannot be upgraded to Build 16.0.6769 or higher (for example, because Excel was installed using a single Office license), purchase a current Office version or use Online Office.

IIS settings for standalone installation of the Excel Add-In

To install the Excel Add-In on a PC without Unified Runtime, the same IIS (Internet Information Services) settings must be active in Windows that are required to install WinCC Unified Runtime on a PC.

You can find additional information in the "SIMATIC Unified PC Installation" user help section on the software and hardware requirements.

Unified Comfort Panel

The following restrictions apply to generating reports on Unified Comfort Panels:

Contexts	Contexts are not supported in V17 for Unified Comfort Panel. This option is not available in a report template with a Unified Comfort Panel as data source. When you generate a report on a Unified Comfort Panel whose report template uses this option, error entries are generated in the "ErrorLog" worksheet of the report.
Storage location of the Reporting database	The following folder on the SD card plugged into the panel is preconfigured as the storage location of the reporting database: • Device version V18: `media/simatic/X51/Reports` You can configure and load another storage location in TIA Portal in the Runtime settings of the Panel. • Device version <V18: `media/simatic/X51`
Storage location for reports	The "Reports" folder on the SD card inserted in the Panel is permanently pre-configured as the local main storage location for reports: `media/simatic/X51/Reports` For Panels with device version V18, you can configure and load a different local main storage location in the Runtime settings of the Panel in TIA Portal.

Enable Reporting

The use of Reporting requires that the Reporting functionality was enabled:

- For configuring report templates:
  Reporting must be enabled for the Runtime project that serves as the data source.
- For configuring report jobs and generating reports in Runtime as well as in a simulation:
  Reporting must be enabled for the Runtime project that is running on the HMI device or is being simulated.

The reporting functionality of a Runtime project is enabled in TIA Portal in the Runtime settings of its HMI device with the option "Enable reporting".

Note

Devices with a device version lower than V18

Reporting is always enabled for HMI devices with a device version lower than V18.

Version compatibility (Page 7651)

Configuring Reporting-specific Runtime settings (Page 7655)

19.2.1.4 Version compatibility

Introduction

When loading a Runtime project for which the "Reports" control has been configured, the general rules for version compatibility of WinCC Unified apply.

The rules described here also apply for the interaction between add-in, data source, report template and runtime version of the project in which reports are generated.

Compatibility between add-in and data source

The add-in can use the following data sources:

Add-in	Online data source	Offline data source
V16	Runtime project V16	Configuration file generated with a Runtime project V16
V17	Runtime project V16 or V17	Configuration file generated with a Runtime project V16 or V17

Compatibility between add-in and report template

The following report templates can be opened and edited in the add-in:

Add-in	Report template
V16	Created with a V16 add-in
V17	• Created with a V17 add-in • Created with a V16 add-in If the add-in is connected to a V17 data source when you open the report template, you will be prompted to migrate the report template to V17. If the add-in is connected to a V16 data source when the report template is opened, no migration is necessary.

Note

Migration of report templates

The migration of the report template is not reversible. A report template migrated from V16 to V17 can no longer be opened in a V16 add-in.

If migration is not desired, connect the add-in to a V16 data source before opening the report template.

Note

Scope of functions of report templates

The functions available in the configuration of the report template in the add-in depend on the version of the data source used by the add-in.

Compatibility between report template and runtime project

In a runtime project, reports can be generated using the following report templates:

Report template	Version of the runtime project
V16	V16 and V17
V17	V17

Basics on version compatibility (Page 187)

19.2.2 Complete workflow for using production reports

Introduction

The use of reports (production reports) requires preliminary work in the Engineering System, in the Excel add-in and in Runtime. The exact workflow depends on where the report template for generating the report is used:

- Internally in the project
  A report template is based on Project A. It is used in Runtime in Project A to generate reports.
- Across projects
  A report template is based on Project A. It is used in Runtime in Project B to generate reports. Project A and Project B were downloaded into the same Runtime.
  The data source items added to the report template must be findable in both projects. Make sure that the names are consistent or that you have a uniform plant model.
- Across Runtimes
  A report template is based on Project A. It is used in Project B to generate reports. Project A and Project B were downloaded into different Runtimes.
  In this case, the following applies:
  - The data source items added to the report template must be findable in both projects. Make sure that the names are consistent or that you have a uniform plant model.
  - In both Runtimes, the same options that are used in the report template must be installed.

Workflow for cross-project use of report templates in the same Runtime

1. In the Engineering System, configure the HMI device that serves as data source for the Excel add-in during configuration of the report templates.
   - Configure alarms and tags.
   - When reports are to evaluate context data, configure the plant model as well as other objects and settings that are necessary to start system-generated contexts.
     Example: To evaluate shift contexts of the Calendar PI option, you configure the plant model, the time model, a calendar and a calendar control.
   - Enable Reporting in the Runtime settings of the device.
2. Select one of the following options:
   - To create the report template before the HMI device goes live, start a simulation for the HMI device.
     Requirement: The engineering system and Runtime are installed on the same device.
     The device is downloaded to Runtime. Its project (project A) is started in simulation mode.
   - To create the report template during productive operation of the HMI device, load the device from the Engineering System into the Runtime and start its project (project A).

   Note

   Evaluation of context-relevant data

   To ensure that reports generated in runtime evaluate context-relevant data, contexts must be executed in the project during runtime.

   The system-generated contexts of the PI options Performance Insight and Calendar are started automatically while a project is running in Runtime.

   You can also use the ODK API to write a program that defines, starts and stops user-defined contexts for a project.

3. (Optional) To work with an offline connection in the Excel add-in, export an offline configuration file in the "Reports" control in Runtime.
4. Start the Excel add-in and set up the data source.
   Select one of the following options:
   - Online connection: Select the Runtime server onto which you loaded the HMI device.
   - Offline connection: Load the offline configuration file created in Step 3 as the data source.
5. Configure a report template in the Excel add-in.
6. (Optional) Test a report template by running it in the Excel add-in and reading the project data into Excel.

7. In the Engineering System, configure the HMI device for which you want to generate reports in Runtime:
   - Place the "Reports" control in one of the screens of the HMI device.
   - Configure alarms, tags and the plant model if the reports are to evaluate context data. Make sure that this data matches the data of the HMI device from step 1.
   - Enable Reporting in the Runtime settings of the device.
   - (Optional) In the Runtime settings of the device, configure the storage location for reports and the storage location of the reporting database.
8. Load the HMI device from the engineering system into Runtime and start its project (Project B).
9. In Runtime, go to the screen with the "Reports" control.
10. (Optional) To send emails when reports are created, configure the global email settings.
11. Configure the job parameters.
    To do this, import the report template defined in step 4, among others.
12. Configure a report job that uses the report template.
13. (Optional) Perform report orders manually.
14. In the control, get an overview of which reports have been generated.
15. Download the reports, if necessary.
16. (Optional) To reuse the configuration of the "Reports" control, such as on a device in another network, transfer the existing configuration from the control from one device to the control of the other device.

19.2.3 Configuring production reports in the engineering system

19.2.3.1 Configuring Reporting-specific Runtime settings

Procedure

1. Open "Runtime settings > Reporting" in the project tree below the HMI device.
2. Select the "Enable Runtime" option.
   When the option is disabled, it is not possible to use the Runtime project as data source for report templates or configure report jobs in Runtime and generate reports.
3. (Optional) Configure the storage location of the reporting database.
4. (Optional) Configure the storage location for the reports generated in Runtime.

You can find more information on configuring these storage locations for Unified Comfort Panel here (Page 7145), for Unified PC here (Page 7180).

19.2.3.2 Inserting a "Reporting" control in a screen

Procedure

1. Select the HMI device on the "Devices" tab.
2. Open the "Screens" folder.
3. Open the screen.
4. In the "My controls" pane, select the "Reporting" control and place it on the screen.

19.2.4 Creating report templates for production reports

19.2.4.1 Requirements

General requirements and restrictions

Installing the Excel add-in

The installation of the Reporting add-in on a computer requires that the operating system and the local MS Excel installation are regularly updated.

If there are problems with the installation, check the version of the local MS Excel installation. Lengthy maintenance intervals between the operating system and Excel can cause problems during installation of the add-in.

Update the operating system and the Excel version if necessary.

To install the add-in with a local Excel installation, MS Excel with build 16.0.6769 or higher is required.

Note

Note the Microsoft upgrade restrictions

If you have an Excel installation that cannot be upgraded to Build 16.0.6769 or higher (for example, because Excel was installed using a single Office license), purchase a current Office version or use Online Office.

IIS settings for standalone installation of the Excel Add-In

To install the Excel Add-In on a PC without Unified Runtime, the same IIS (Internet Information Services) settings must be active in Windows that are required to install WinCC Unified Runtime on a PC.

You can find additional information in the "SIMATIC Unified PC Installation" user help section on the software and hardware requirements.

Unified Comfort Panel

The following restrictions apply to generating reports on Unified Comfort Panels:

Contexts	Contexts are not supported in V17 for Unified Comfort Panel. This option is not available in a report template with a Unified Comfort Panel as data source. When you generate a report on a Unified Comfort Panel whose report template uses this option, error entries are generated in the "ErrorLog" worksheet of the report.
Storage location of the Reporting database	The following folder on the SD card plugged into the panel is preconfigured as the storage location of the reporting database: • Device version V18: `media/simatic/X51/Reports` You can configure and load another storage location in TIA Portal in the Runtime settings of the Panel. • Device version <V18: `media/simatic/X51`
Storage location for reports	The "Reports" folder on the SD card inserted in the Panel is permanently pre-configured as the local main storage location for reports: `media/simatic/X51/Reports` For Panels with device version V18, you can configure and load a different local main storage location in the Runtime settings of the Panel in TIA Portal.

Enable Reporting

The use of Reporting requires that the Reporting functionality was enabled:

- For configuring report templates:
  Reporting must be enabled for the Runtime project that serves as the data source.
- For configuring report jobs and generating reports in Runtime as well as in a simulation:
  Reporting must be enabled for the Runtime project that is running on the HMI device or is being simulated.

The reporting functionality of a Runtime project is enabled in TIA Portal in the Runtime settings of its HMI device with the option "Enable reporting".

Note

Devices with a device version lower than V18

Reporting is always enabled for HMI devices with a device version lower than V18.

Version compatibility (Page 7651)

Installation of the Reporting add-in

Note

Regular updates of operating system and MS Excel

The installation of the Reporting add-in on a computer requires that the operating system and the local MS Excel installation are regularly updated.

If there are problems with the installation, check the version of the local MS Excel installation. Lengthy maintenance intervals between the operating system and Excel can cause problems during installation of the add-in.

Update the operating system and the Excel version if necessary.

To install the add-in with a local Excel installation, MS Excel with build 16.0.6769 or higher is required.

Note

Note the Microsoft upgrade restrictions

If you have an Excel installation that cannot be upgraded to Build 16.0.6769 or higher (for example, because Excel was installed using a single Office license), purchase a current Office version or use Online Office.

Procedure

1. Install the Excel manifest on the computer.
2. Set up read access to the installation path of the Excel manifest.
3. Add the add-in to Excel.

See also

Installing the Excel manifest (Page 7658)

Setting up read access to the Excel manifest (Page 7658)

Adding the Reporting add-in in Excel (Page 7659)

MS help for autoloop (https://docs.microsoft.com/en-us/office/troubleshoot/error-messages/cannot-open-add-in-from-localhost)

Installing the Excel manifest

Procedure

1. In the installation package of WinCC Unified on "DVD_2", double-click the file "Support\Reporting\SIMATIC_WinCC_Unified_Reporting_<Version number>.exe".
2. Select the target directory to which the underlying ZIP file is extracted and confirm your input. The ZIP file is extracted and setup starts automatically.

   Note

   Start setup manually

   To start the setup manually after the file was extracted, select the option "Extract the setup files without being installed".

   Start the setup later by running the "Setup.exe" file as administrator in the target directory.

3. Follow the setup instructions.
4. In the "Configuration" step, select the option for the Excel add-in.
5. Click "Next" and follow the setup instructions.

See also

Installation of the Reporting add-in (Page 7657)

Setting up read access to the Excel manifest

Requirement

The Excel manifest is installed.

Procedure

Give the users that create templates with the Excel add-in read access to the installation path of the Excel manifest: <target directory>\WinCCUnifiedReporting\Excelmanifest

Note

This step is also necessary if the user belongs to a group in the user management with general read permission.

See also

Installing the Excel manifest (Page 7658)

Installation of the Reporting add-in (Page 7657)

Adding the Reporting add-in in Excel

Requirement

- The Excel manifest is installed on the PC.
- Read access to the installation path of the Excel manifest is set up.
- The following software is available on the computer:
  - Local Excel
    MS Excel (Build 16.0.6769 or higher)

    Note

    Regular updates of operating system and MS Excel

    The installation of the Reporting add-in on a computer requires that the operating system and the local MS Excel installation are regularly updated.

    If there are problems with the installation, check the version of the local MS Excel installation. Lengthy maintenance intervals between the operating system and Excel can cause problems during installation of the add-in.

    Update the operating system and the Excel version if necessary.

    Note

    Note the Microsoft upgrade restrictions

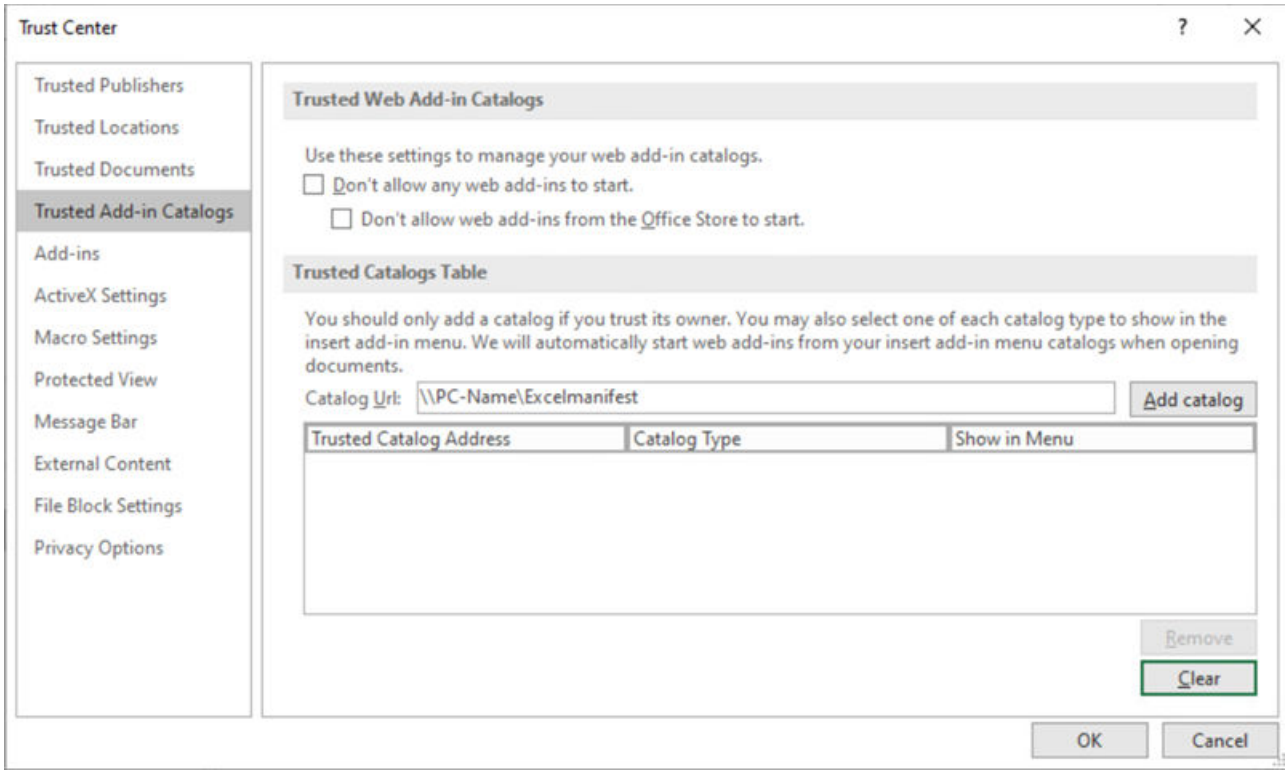
    If you have an Excel installation that cannot be upgraded to Build 16.0.6769 or higher (for example, because Excel was installed using a single Office license), purchase a current Office version or use Online Office.

  - Or Office online

Procedure

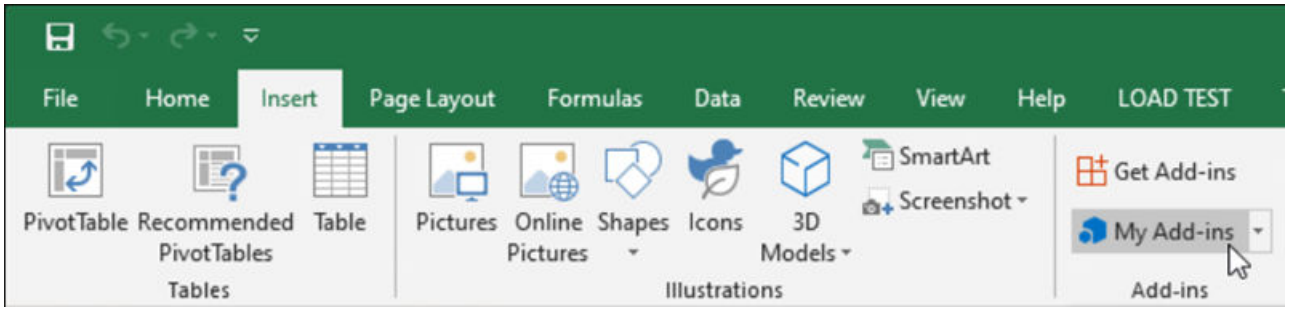
1. Open Microsoft Excel.
2. Open the "Trust Center" under "File" > "Options".
3. Click "Trust Center Settings".
4. Click "Catalogs of trusted add-ins".

5. Add the catalog using the URL "\\<Computer name>\Excelmanifest".



6. Make sure that the check mark in the "Show in Menu" column is set.
7. End and restart Excel.

8. In the "Insert" menu, click "My Add-ins".



In the "Office Add-ins" dialog box, the Siemens add-in is displayed under "Shared folders".

9. Select the add-in and click "Add".

Installation of the Reporting add-in (Page 7657)

Configuring Internet Explorer and Edge

The Reporting Excel add-in uses the certificate that was selected during installation of WinCC Unified Runtime or later in "WinCC Unified Configuration".

Some browsers do not consider self-signed certificates as trusted. If you use a self-signed certificate for WinCC Unified Runtime, you must add the certificate to the list of trusted certificates in Internet Explorer or Edge on the device on which the Excel add-in is installed.

For detailed information on handling certificates, see the Runtime Readme.

Procedure

The following section describes the procedure for adding a self-signed certificate to the list of trusted certificates, using Internet Explorer as an example:

1. Start Internet Explorer.
2. In the address line, enter the host name or the IP when creating the certificate.
   You will receive a security warning.
3. Click "Continue to this website (not recommended)".
4. Click "Install certificate".
5. Click "Place all certificates in the following store" and "Browse".
6. Click "Trusted Root Certification Authorities" followed by "OK".

   Note

   Do not use the preset options for automatic selection of the certificate store.

7. Exit the dialog.
8. If you receive a security warning as to whether you want to trust the certificate, confirm it with "Yes".
9. Load the page again.

See also

MicrosoftHelp_IE_ZertifikatInstallieren (https://medium.com/@ali.dev/how-to-trust-any-self-signed-ssl-certificate-in-ie11-and-edge-fa7b416cac68)

19.2.4.2 Login

A login dialog opens in the Excel add-in in the following cases:

- After start of Excel and the add-in
- When using an online connection: When the connection to the Runtime server must be re-established.
  Examples:
  - Runtime has been reloaded.
  - The security token has expired due to a timeout.

Requirement

- The add-in is installed.
- When using an online connection:
  - A Runtime server is accessible.
  - A Runtime project is running on the server.

Procedure

In order to use an online connection, log onto a Runtime server:

1. Under "Server", enter the name of the server on which the project that is to serve as data source for the report template is running.
   Use the same spelling as when the Runtime server certificate was created.

   Note

   If Runtime is installed on the same computer as the add-in, use of the name "localhost" is not permitted.

2. Enter the user name and password of a user that is registered on the server in the Runtime user management.
3. Click "Login".

In order to use an offline connection, click "Go offline".

Result

Online connection

The add-in is connected to the Runtime server and the options available there are loaded.

You can now create report templates.

Offline connection

Before you create report templates, set up the offline connection.

See also

Setting up an offline connection (Page 7666)

Installation of the Reporting add-in (Page 7657)

19.2.4.3 Setting up a data source

Using an online connection

When an online connection is present, the add-in establishes a connection to a Runtime server. The project running on the server serves as data source for the add-in.

The connection settings allow you to:

- Change the connected Runtime server to another Runtime server
- When a report template that was created with a different Runtime server than the currently connected server is reused: check the options available on the server and delete the options that were not loaded

Setting up an online connection

Requirements

- A Runtime server is accessible.
- A Runtime project is running on the server.

Procedure

1. In the "Data sources" group on the "WinCC Unified" tab, click on "Connections".
2. Click "Online" under "Connections" in the add-in.
3. Under "Server", enter the server name.
   Use the same spelling as when the Runtime server certificate was created.

   Note

   If Runtime is installed on the same computer as the add-in, use of the name "localhost" is not permitted.

4. Click "Load".

Result

- A server node is created.
- The add-in is connected to the Runtime server and its options are loaded.
  Data source items of these options can be added to report templates. Their data can be read in from Runtime to Excel.

  Note

  To check which options were loaded, click on the server node.

  Options that are being used in the currently open report template but are not available on the connected server have a red icon. You can remove the option:

- If no connection can be established or an incorrect server name has been entered, the add-in will display a corresponding error message.

See also

Removing options (Page 7664)

Removing options

Introduction

If you reuse report templates across servers, e.g. in order to adapt an existing template for another project, it may be necessary to remove unavailable options from the connection settings.

The procedure for this is presented using the Performance Insight option as an example.

Requirement

- The add-in was connected to a server on which the Performance Insight (PI) option is installed.
- A report template that uses KPIs was created with the add-in.
- The add-in was then connected to a server without the Performance Insight option installed for the purpose of adapting the template to the project running there.

Removing an option

1. In the "Data sources" group on the "WinCC Unified" tab, click on "Connections".
2. Under "Connections", click on "Online".
3. Select the server node.
   You see the loaded options under the server node:

	Available options The following applies to data source items of these options: • They can be added to the report template. • Their data can be read in from Runtime to Excel in the add-in.
	Unavailable options In the example: Performance Insight The following applies to data source items of these options: • They cannot be added to the report template. • If the report template already has a data source element of this option, its data cannot be read in from Runtime to Excel.

4. Select the "Performance Insight" option under the server node.
5. Click the "Delete" button next to the option.
6. Confirm your input.

Result

The option is removed from the connection settings.

Next, remove all data source items of this option from the report template.

Reloading an option

When the add-in is connected to a Runtime server, all options available on the server are loaded.

To reload an option that was deleted in the connection settings but is available on the server, select the server node and click "Load".

Using an offline connection

With the offline connection, the add-in uses a configuration file as data source.

The connection settings allow you to:

- Change the configuration file used
- When reusing a report template with a configuration based on a Runtime server different to that of the currently selected configuration file: Check the available options and delete the options that were not loaded.

Setting up an offline connection

Requirement

An offline configuration file was created in the "Reports" control in Runtime. The configuration file is available on the device.

Procedure

1. In the "Data sources" group on the "WinCC Unified" tab, click on "Connections".
2. Under "Connections", click on "Offline".
3. Click "Open offline configuration".
4. Select the desired file in the window that opens and confirm your entries.
5. Click "Load".
6. Select the desired options.
7. Confirm your entries.

Result

- A server node is created. The node bears the name of the server on which the configuration file is based.
- The configuration file, together with its options, is loaded into the add-in. The data of the configuration file is available for configuring the report template.

Note

To check which options were loaded, click on the server node.

Options that are being used in the currently open report template but are not available in the configuration file have a red icon. You can remove the option:

See also

Removing options (Page 7667)

Exporting an offline configuration file (Page 7743)

Removing options

Introduction

If you reuse report templates across servers, e.g. in order to adapt an existing template for another project, it may be necessary to remove unavailable options from the connection settings.

The procedure for this is presented using the Performance Insight option as an example.

Requirement

- The add-in was changed over to an offline connection whose configuration file does not include Performance Insight.
- A report template was opened in the add-in whose configuration is based on a connection to a Runtime server on which Performance Insight is installed.

Removing an option

1. In the "Data sources" group on the "WinCC Unified" tab, click on "Connections".
2. Under "Connections", click on "Offline".
3. Select the server node.
   You see the loaded options under the server node:

	Available options The following applies to data source items of these options: • They can be added to report templates. • Their data can be read in from the configuration file to Excel.
	Unavailable options In the example: Performance Insight The following applies to data source items of these options: • They cannot be added to the report template. • If the report template already has a data source element of this option, its data cannot be read in from the configuration file to Excel.

4. Select the "Performance Insight" option under the server node.
5. Click the "Delete" button next to the option.
6. Confirm your input.

Result

The option is removed from the connection settings.

Next, remove all data source items of this option from the report template.

Reloading an option

When a configuration file is loaded, all options available in the file are loaded.

To reload an option that was deleted in the connection settings but is available in the configuration file, select the server node and click "Load".

19.2.4.4 Configuring report templates

Requirement

An online connection or offline connection has been established.

Procedure

To create a new report template, proceed as follows:

1. Open a new Excel file.
2. Add a segment.
   You can choose between time series segments and single value segments.
3. Add data source items to the segment.
   The exact procedure depends on the type of the data source item.
4. Optional: If you do not want a data source item to use the default configuration, determine its configuration.
   You have the following options:
   - Select an existing configuration.
   - Create a new configuration and select it.
   - Define a local configuration.
5. Optional: To define additional segments, repeat steps 2 to 4.
6. Optional: When using an online connection, test the template by reading the runtime data of selected segments or all segments.

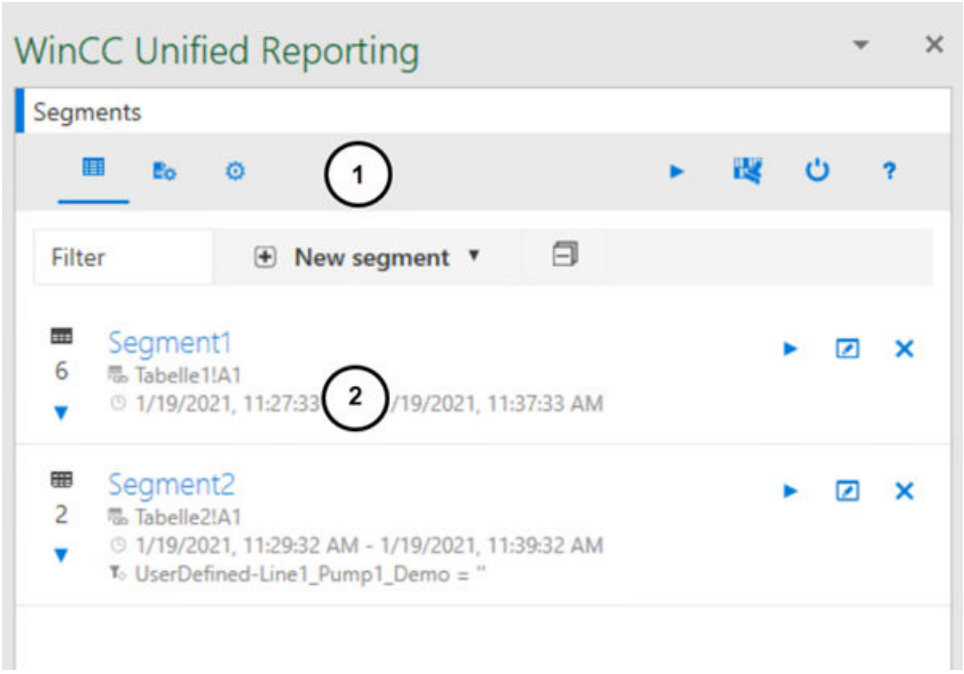
User interface of the add-in

Requirement

- The "WinCC Unified" tab is visible in Excel.

Structure

If you click on "Segments" in the "Configuration" group, you see the following interface:



① Toolbar
② Work area

Toolbar buttons:

Button	Tooltip	Description
	"Segment configuration"	Loads the interface to add and edit segments in the work area.
	"Data source item configuration"	Loads the interface for adding and editing the configuration of a data source item in the work area.
	"Basic settings"	Loads the interface for setting the language settings in the work area.
	"Update all"	Reads the Runtime data of the connected data source into the data tables of the segments.
	"Delete Runtime data"	Removes all Runtime data from the report template.
	Logoff	Logs out the user currently logged in to the add-in.
	Help	Opens the user help for the add-in.

Working with segments

Basic information on segments

Definition

A report template consists of any number of segments. Each *segment* is a container to which you can add any number of data source items. The segment reads the data from its data source items.

There are time series segments and single value segments.

Note

Hierarchical segments of PI options

Hierarchical segments are also available with PI Options installed. For more information on this, refer to the PI Options help.

Time series segments

A *time series segment* documents the data of its data source items in a defined time period.

It has a legend table and a data table.

Data source items

Time series segments can have the following data source items:

- Logging alarms
- Alarm statistics
- Logging tags
- User-defined columns
- Contexts
- Audit

Note

Data source items of the PI options

If PI options are installed, additional data source items can be added. For more information on this, refer to the PI Options help.

Legend table

The table header row provides general information about the segment and its data source items.

You decide which type of information is provided when you create or edit the segment.

Data table

The data table outputs the data of the data source items. It documents how the data source items have changed in the defined time period.

The data table of a time series segment has the following columns:

Columns		Description
Time stamp column		Always output Always output as the first column
Per data source item	Standard column	The standard column provides the standard property of the data source item. This property depends on the type of data source item. For a data source item of the Tag type, e.g. the tag value
	Optional columns	Provide more information about the data source item. What information this is depends on the type of the data source item. For a data source item of the Tag type, e.g. the quality code of the tag value You change the default settings for visibility, column title and order of these columns in the configuration of the data source item.

In the default setting, the data source items in the data table have the order in which they were added to the segment.

Note

When the standard columns and optional columns provide numerical values, you can have the actual values replaced with texts or graphics from a text list or graphic list when importing the Runtime data.

Single value segments

A *single value segment* documents exactly one value for its data source items.

Data source items

Single value segments can have the following data source items:

- Logging tags
- Tags

Note

Data source items of the PI options

If PI options are installed, additional data source items can be added. For more information on this, refer to the PI Options help.

Data table

The data table of a single value segment has the following columns per data source item:

Columns	Description
Standard column	The standard column provides the standard property of the data source item. For tags and logging tags: the tag value
Optional columns	Provide more information about the data source item. For tags and logging tags: • Time stamp • Data source item • Quality code of the tag value You change the default settings for the visibility of these columns in the configuration of the data source item.

The data table of a single value segment shows the data source items in the order in which they were added to the segment.

Note

When the standard columns and optional columns provide numerical values, you can have the actual values replaced with texts or graphics from a text list or graphic list when importing the Runtime data.

Single row segments do not have a table header row. However, in the configurations of their data source items, you can determine whether a caption is inserted for the displayed columns and the position at which this occurs.

See also

Standard column (Page 7672)

Standard column

Introduction

For each data source item of a segment, a standard column is added in the data table of the segment.

Content of the standard column

The standard column provides the standard property of the data source item and depends on the type of the data source item:

Data source item type	Default column title	Value
Logging alarm	"Alarm ID"	Alarm IDs of the displayed alarms
Alarm statistics	"Alarm statistics [ID]"	Alarm IDs of the alarms displayed in the alarm statistics

Data source item type	Default column title	Value
Tag or logging tag	"<Name of the tags or logging tags>"	Value of the tag or logging tag
Context	"<Name of the context object>"	Context name
Audit	"Audit [<object name>]"	The name of the object monitored by the Audit Trail
User-defined column	Name entered when creating the data source item	As set in the configuration of the data source item: • A fixed string. Or • A dynamically calculated string

Changing the column title

You can replace the default column title with a localizable display name. See Setting a display name for standard column (Page 7711).

Replacing numerical values

If the standard column provides numeric values, you have the option to have the actual values replaced with texts or graphics from a text list or graphic list when the Runtime data is read in. See Assigning text lists and graphic lists (Page 7708).

User-defined columns are excluded from this.

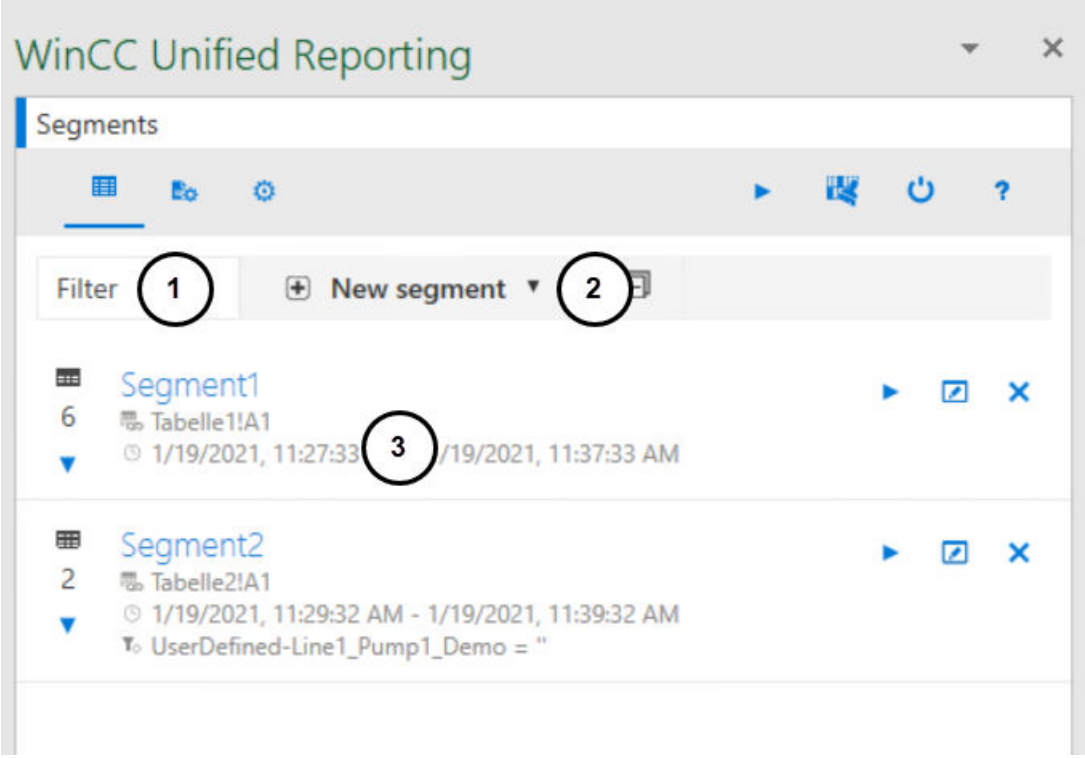
See also

Basic information on segments (Page 7670)

The segment user interface

Structure

The interface for creating and editing segments has the following structure:



① Filter
Filters the list of segments by name.

② Button for creating a segment

③ List of segments
Each segment has buttons for reading in, editing and deleting the segment.
The following configuration is displayed for each segment:

- Segment name
- Number of data source items
- Insertion location of the segment in the Excel file
- Time span
- If context filters have been configured: The filter string

A click on the segment opens the area with the data source items.

Create segments

Requirement

- The "WinCC Unified" tab is visible in Excel.
- The data source is set up.
- To filter the time interval of the time series segment depending on the context: There are contexts in the project that run on the connected Runtime server or are the basis of the configuration file.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click "New segment".
3. Select "New time series segment" or "New single value segment".
4. Enter a segment name.

Note

Note the Excel restrictions for naming tables (for example, do not use blanks).

Change the segment name only via the add-in, not via the Excel property "Table name".

Do not change the name of the worksheet after creating the segment. The add-in addresses the segment by the segment name and the worksheet name.

5. For a time series segment, make the following settings in addition:
   - Under "File location" you determine where the segment will be inserted in the file. Enter the name of the worksheet and the cell.
     Alternatively, click "Select a cell" and use the cell currently selected in the Excel file:

     
   - Under "Start" and "End", you determine the time period for which values are read into the segment.

	"Absolute date/ time"	Select a date and a time. The information is absolute to the current date.
	"Relative date/ time"	Select a reference time and a time interval. The information is relative to the current date. See also Formats for relative time information (Page 7679).
	"Date/Time of the cell"	Applies the value of the cell currently highlighted in the Excel file. Make sure that the cell supplies a valid time.
	"Date/Time of the tag"	Applies the value of the set tag. Make sure that the tag supplies a valid time. Possible data types: • DateTime • String • Integer

– (Optional) Under "Properties of the legend table", you configure the contents to be displayed in the table header row of the segment:

"Name" "Start" "End" "State"	General information on the segment
"Context filter"	If the segment time was limited by a context filter: The filter string is output. See step 6.
"Audit status"	If the segment has an audit data source item, the field shows the overall status of the audit data: • Green field: No manipulations of the Audit Trail were found in the queried time range. • Red field: Manipulations of the Audit Trail were found in the queried time range. Single or multiple entries have been deleted, added or changed.
"Header"	The table header row includes a list of the segment's data source items showing general information about these data source items. The information displayed for the data source items depends on their type. Example of contexts: Display name of the context, context provider, hierarchy path, short name of the context, full name of the context, option

Use the check boxes to remove information from or add information to the legend table. To change the sorting in the table header row, move the mouse pointer to a row and shift it using the arrow buttons or drag-and-drop.

6. (Optional) You can filter the time interval of the time series segment depending on the context. You can define up to two filter conditions.
   Proceed as follows:
   - Under "Context filter", click "+" or "Add new condition row".
     The condition line is added.
   - Click on "+" in the condition line.
   - Under "Select context", select the root of the common plant model.
     In the next row, you see the top level of the common plant model.
   - Navigate through the common plant model to plant objects with contexts.
     Plant objects and contexts can be recognized by the following icons:

	Plant object
	Context

   - Select a context.
   - Select an operator.
   - Enter a value.
   - (Optional) Use "+" or "Add new condition row" to create a second condition and select whether the two conditions are to be linked with a logical AND or OR.
7. (Optional) Under "Autofit", configure whether the column width and row height of the data table is automatically adapted to the text read from Runtime.
8. Confirm your entries with "OK".

Result

The segment is created and added to the list of segments:

Next, add data source items to the segment. Your procedure depends on the type of the new data source item.

Tips on design and layout (Page 7717)

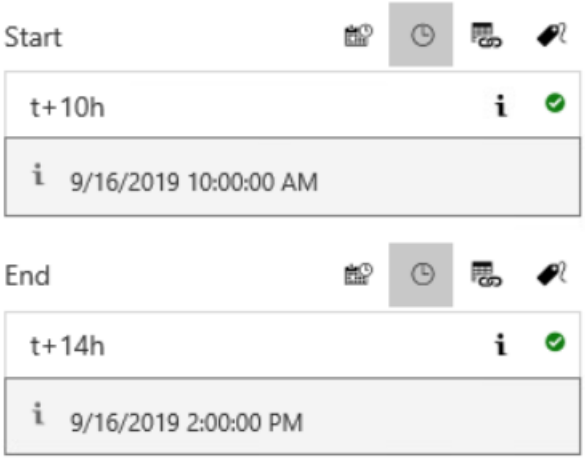
Adding data source elements (Page 7681)

Working with configurations (Page 7694)

Formats for relative time information

Definition of a relative time information

The relative times are entered using a reference time and a time interval.



Reference time

Use one of the following characters for the reference time:

- "*" - Now
- "t" (today) - Today at midnight
- "y" (yesterday) - Yesterday at midnight
- "1-31" - Specific day of the current month

Time interval

- "y" (year): +1y = plus 1 year
- "mo" (month): +1mo = plus 1 month
- "w" (week): +1w = plus 1 week
- "d" (day): +1d = plus 1 day
- "h" (hour): +1h = plus 1 hour
- "m" (minute): +1m = plus 1 minute
- "s" (second): +1s = plus 1 second
- "ms" (milliseconds): +250ms = plus 250 milliseconds

Examples

- *-1y: One year ago today
- t+8h: Today at 8:00 am
- y+8h: Yesterday at 8:00 am
- 1+8h: The first day of the current month at 8:00 am
- *-1d: One day ago
- *-2h-30m-30s: 2 hours, 30 minutes and 30 seconds ago

See also

Create segments (Page 7675)

Edit segments

Requirement

- The "WinCC Unified" tab is visible in Excel.
- A segment is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click "Edit" next to a segment in the list of segments.
3. Edit the segment.
   You can make the same settings as when creating the segment.

Delete segments

Requirement

- The "WinCC Unified" tab is visible in Excel.
- A segment is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click "Delete" next to a segment in the list of segments.
3. Confirm your entries with "OK".

Adding data source elements

Adding log alarms

Requirement

- There are logging alarms in the project that runs on the connected Runtime server or is the basis of the configuration file.
- The "Alarm" option is enabled in the connection settings.
- The "WinCC Unified" tab is visible in Excel.
- A time series segment is available.

Adding logging alarms

1. Click on "Segments" in the "Configuration" group.
   The list with the segments already created is loaded into the add-in.
2. Select a segment.
   The segment is extended by the area for the data source items.
3. Click "+".
4. Select the "Alarms" option.
5. Select the "Alarm" entry under "Select alarms".
6. Under "Select alarms", select the entry "Alarm [ID]".

   Note

   Change selection criteria

   After you have added alarms, you can change the selection criteria and add more data source items to the segment.

   For example: Output tags and alarms in the same segment.

7. To cancel your selection, select the entry "Alarm [ID]" under "Selected data source items" and click "Delete".
8. Confirm with "OK".

Result

- The data source item for logging alarms is added to the add-in below the segment.
- The configuration of the data source item controls which data is added when importing the runtime data into the data table.

  Note

  With the default setting, the data source item uses the default configuration. It shows all logging alarms of the project.

To display data that deviates from the default configuration, select one of the following options:

- Select a different matching configuration.
- Create your own configuration.
- Edit a configuration.
- Overwrite a configuration locally.

See also

Creating or editing configurations for log alarms (Page 7694)

Select configuration (Page 7705)

Working with configurations (Page 7694)

Adding alarm statistics

Introduction

To output statistical calculations for logging alarms in a report, add alarm statistics to a report template. The following calculations are available:

- Frequency of an alarm
- Average display time per state machine
- Total display time per state machine
- Maximum display time per state machine
- Minimum display time per state machine

The alarm statistics add columns with statistical calculations and columns with general alarm properties of the recorded alarms to the reports.

You can find more information about calculations in alarm statistics in the help for the alarm control.

Requirement

- The "Alarm" option is enabled in the connection settings.
- The "WinCC Unified" tab is visible in Excel.
- A time series segment is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
   The list with the segments already created is loaded.
2. Select a time series segment.
   The segment is extended by the area for the data source items.

3. Click "+".
4. Select the "Alarm" option.
5. Under "Select alarms", select the entry "Alarm statistic [ID]".
6. Under "Select alarm statistic" select the entry "Alarm statistic [ID]".

Note

Change selection criteria

After adding the alarm statistics, you can change the selection criteria and add more data source items.

7. (Optional) To cancel your selection, select the entry "Alarm statistic [ID]" under "Selected data source items" and click "Delete".
8. Confirm with "OK".

Result

The added data source item for alarm statistics is displayed below the segment and inserted into the data table.

First, the data table shows the contents configured in the default configuration for alarm statistics. To output other contents, select or create a configuration.

Creating or editing configurations for an alarm statistics (Page 7696)

Working with configurations (Page 7694)

Add logging tags

Requirement

- The project on which the connected Runtime server runs or the basis of the configuration file has logging tags.
- The "Logging tag" option was selected while setting up of the connection.
- The "WinCC Unified" tab is visible in Excel.
- A single value segment or time series segment is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
   The list of segments is loaded.
2. Select a segment.
   The segment is extended by the area for the data source items.
3. Click "+".

4. Select the "Logging tag" option.
5. Optional: To reduce the load time, filter which tags are loaded to the selection under "Add filter".
   The preset filters "*" return all logging tags of the project.
   – "Tag name": Enter the name of the tag whose logging tags you want to add.
   – "Logging tag name": Enter the name of the logging tags you want to add.

   Note that the entry is case-sensitive.

   Note

   Filter by partial string

   You use the wildcard "*" to filter by partial strings.

   For example:
   - *T* returns all tags with a "T" in their name.
   - *T returns all tags that end in "T".
   - T* returns all tags that start with "T".

   When filtering for structures, the separators must be part of the filter string.

   For example: The following filters return the logging tags for all tags of the device "HMI_RT_1":
   - Filter for tag: "HMI_RT_1::*"
   - Filter for logging tag: "*"
6. Click "Load".
   The logging tags of the project are filtered and provided under "Select tags".
7. Optional: Further reduce the number of tags that are offered for selection by clicking next to "Select logging tags" and entering another filter string.
   The list of tags you are being offered is filtered while you type.
8. Select one or more tags under "Select logging tags".
   The tags are added to the "Selected data source items" list.

   Note

   Change selection criteria

   After you have added a tag, you can select a different option or a different filter and add additional data source items.

   For example: Output KPIs and logging tags in the same segment.
9. To remove one or more data source items from "Selected data source items", select them and click "Delete".
10. Confirm with "OK".
    The added logging tags are shown below the segment and added to the Excel table.
11. If you have added the logging tag to a single value segment:
    – In the Excel worksheet, select the cell in which the logging tag is to be inserted.
    – Click the "Select a cell" button on the data source item of the logging tag.
      Alternatively, enter the name of the worksheet and the cell.

Create segments (Page 7675)

Select configuration (Page 7705)

Create or edit configurations for logging tags (Page 7697)

Working with configurations (Page 7694)

Adding tags

Requirement

- The project on which the connected Runtime server runs or the basis of the configuration file has tags.
- The "Tag" option was enabled when the connection was set up.
- The "WinCC Unified" tab is visible in Excel.
- A single value segment is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
   The list of segments is loaded.
2. Select the single value segment.
   The segment is extended by the area for the data source items.
3. Click "+".
4. Select the "Tag" option.
5. Optional: To reduce the load time, filter which tags are loaded to the selection under "Add filter".
   Under "Tag name", enter a filter, e.g. the name of the tag. Note that the entry is case-sensitive. The default filter "*" returns all tags of the project.

   Note

   Filter by partial string

   You use the wildcard "*" to filter by partial strings.

   For example:
   - *T* returns all tags with a "T" in their name.
   - *T returns all tags that end in "T".
   - T* returns all tags that start with "T".

   When filtering for structures, the separators must be part of the filter string.

   For example: The filter "HMI_RT_1::*" returns all tags of the device "HMI_RT_1".

6. Click "Load".
   The tags of the project are filtered and provided under "Select tags".
   You can recognize structs and arrays in the list by the following items:

① Button to display the members of the struct or array
② "Select all included data source items"
Button that adds all members with a simple data type to the list of selected data source items

7. Optional: Further reduce the number of tags that are offered for selection by clicking next to "Select tags" and entering another filter string.

   The list of tags you are being offered is filtered while you type.

8. Select which tags will be added to the segment. You have the following options:

Target	Procedure	Result
Show the members of a struct or array.	Click the button with the arrow next to the struct or array.	A second "Select tags" list is added, in which you can see all the members of the struct or array. You can add to the segment any members that have a simple data type, e.g. bool, float or string.
Add all members of a struct or array.	Next to the struct or array, click "Select all included data source items".	All members with a simple data type are added to the "Selected data source items" list and marked as selected under "Select tags":
Select tags with simple data type.	Under "Select tag", click the required tags.	The tags are added to the "Selected data source items" list and marked as selected under "Select tags": 

Note

Automatic filtering when displaying the members or selection of all members

If you click the button to display the members of a struct or array or activate the option to select their members, the struct or array is set as a filter:

- The list under "Select tags" only shows the struct or array.
- A second "Select tags" list is added below this, in which you can see all members of the struct or array.

To see all available tags again, delete the filters.

Note

Change selection criteria

After you have added a tag, you can select a different option or a different filter and add additional data source items.

9. To remove tags from the segment, click on the tags in "Selected data source items" and click "Delete".
10. Confirm with "OK".

The added tags are added to the segment.

When the report template is updated in the add-in and when the report is generated in runtime, the tag values are inserted into the data table.

Creating or editing configurations for tags: (Page 7699)

Working with configurations (Page 7694)

Adding contexts

Introduction

To display in a report which contexts are to run during a certain time period, add only contexts to a segment in the report template.

To display which process data has been accumulated during the runtimes of a context, add the context and other data source items, such as logging tags or logging alarms, to the segment.

Requirement

- There are contexts in the project that run on the connected Runtime server or are the basis of the configuration file.
- The "Context" option is enabled in the connection settings.
- The "WinCC Unified" tab is visible in Excel.
- A time series segment is available.

Adding a context to a segment

1. Click on "Segments" in the "Configuration" group.
   The list with the segments already created is loaded.
2. Select a segment.
   The segment is extended by the area for the data source items.
3. Click "+".
4. Select the "Context" option.

5. Select a context:
   - Under "Select a context definition", select the root of the plant model.
     In the next row, you see the top level of the common plant model.
   - Navigate through the common plant model to plant objects with contexts.
     Plant objects and contexts can be recognized by the following icons:

	Plant object
	Context

   - Select the desired contexts.
     All selected contexts are included in the "Selected data source items" list

Note

Change selection criteria

After you have added a context, you can select a different option and add additional data source items.

For example: Context and logging tags in the same segment.

6. To remove one or more data source items from "Selected data source items", select them and click "Delete".
7. Confirm with "OK".

Result

The selected contexts are displayed below the segment and inserted into the data table.

If you do not want a context to use the default configuration, select its configuration next.

Content of the data table after executing the segment

In segments to which only contexts or contexts and user-defined columns have been added:

- A line is inserted for each context whose runtime falls within the time period of the segment.
- "Time stamp" column: The time at which the context was started

In segments that combine contexts with logging tags or logging alarms:

- All logged values with the same time stamp are displayed per row.
- "Time stamp" column: The logging event
- "Start time" column: The time at which the context was started
- "Context " <Context name>"" column: The value passed to the context at start
- If no context was started at the time of logging, the context cells remain empty.

Example

The following data source items were added to a segment:

- The "Product" context
  Runtime of the context: 15:00:00 to 19:59:59 hours
  The context was started with the "Orange lemonade" value.
- The "Logged_Rotation" logging tag
  Logging cycle: 2s
- The "Logged_Temperature" logging tag
  Logging cycle: 5s
- The user-defined "Unit" column
  It contains the unit for "Logged temperatures".

Content of the data table after execution of the segment:

	A	B	C	D	E	F	G
1	Time stamp	Context "Product"	.../Line1-Product:StartTime	.../Line1-Product:EndTime	Logged_Rotation	Logged_Temperature	Unit
2	Mo, 24 Feb 2020 15:00:00,100	Orange lemonade	Mo, 24 Feb 2020 15:00:00,00	Mo, 24.02.2020 19:59:59,99	10	20	°C
3	Mo, 24 Feb 2020 15:00:02,100	Orange lemonade	Mo, 24 Feb 2020 15:00:00,00	Mo, 24.02.2020 19:59:59,99	100		°C
4	Mo, 24 Feb 2020 15:00:04,100	Orange lemonade	Mo, 24 Feb 2020 15:00:00,00	Mo, 24.02.2020 19:59:59,99	500		
5	Mo, 24 Feb 2020 15:00:05,100	Orange lemonade	Mo, 24 Feb 2020 15:00:00,00	Mo, 24.02.2020 19:59:59,99		40	°C
6	Mo, 24 Feb 2020 15:00:06,100	Orange lemonade	Mo, 24 Feb 2020 15:00:00,00	Mo, 24.02.2020 19:59:59,99	750		°C
7	...	...	...	...	...	...	...
8	Mo, 24 Feb 2020 20:00:00,100				650		°C

Lines 2 to 6	Values were logged for "Logged_Rotation" and "Logged_Temperature", while the "Product" context ran with the "Orange lemonade" value.
Line 8	A value was logged for "Logged_Rotation" while no context was running.

Adding user-defined columns

Introduction

User-defined columns supplement the data of the other data source items of a time series segment with additional information:

- With a fixed string
  The string appears in each cell of the column.
  Example: Display measurement unit of the tag values in report
- With a formula
  The formula is calculated during generation for each cell in the dynamic column.
  Example: The sum of the tag values output in the report.

The configuration of the user-defined column controls which string or formula it uses.

Requirement

- The "User-defined column" option was enabled when the connection was set up.
- The "WinCC Unified" tab is visible in Excel.
- A time series segment is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
   The list of segments is loaded.
2. Select a segment.
   The segment is extended by the area for the data source items.
3. Click "+".
4. Select the option "User-defined column".
5. Enter the name of the column under "name".
6. Click "Select" or press <ENTER>.
   The column is included in the list "Selected data source items".

   Note

   Change selection criteria

   After you have added a column, you can select a different option or a different filter and add additional data source items.

7. Select a configuration for the user-defined column.
8. To remove one or more data source items from "Selected data source items", select them and click "Delete".
9. Confirm with "OK".

The added columns are displayed below the segment and inserted into the data table.

Creating and editing configurations for user-defined columns (Page 7701)

Working with configurations (Page 7694)

Add Audit

Introduction

To output the Runtime device Audit Trail in a report, add an Audit data source item to a report template.

You can find more information about the Audit option in WinCC Unified in the TIA Portal help.

Requirement

- The Audit option was activated in the engineering for the Runtime device.
- The "Audit" option is activated in the connection settings of the Excel add-in.
- The "WinCC Unified" tab is visible in Excel.
- A time series segment is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
   The list with the segments already created is loaded.
2. Select a time series segment.
   The segment is extended by the area for the data source items.
3. Click "+".
4. Select the "Audit" option.
5. Select the Audit Trail.
6. (Optional) To undo your selection, select the Audit Trail under "Selected data source items" and click "Delete".
7. Confirm with "OK".

Result

The Audit data source item is displayed below the segment.

If an Audit Trail is configured for the data source, the Audit data is inserted into the report when the Runtime data is read into Excel and when it is generated in Runtime:

- In the legend table: Identifier of the overall status of the Audit Trail for the queried time range in the "Audit Status" field

Value	Description
Green	No manipulations of the Audit Trail were found in the queried time range.
Red	Manipulations of the Audit Trail were found in the queried time range. Single or multiple entries have been deleted, added or changed.

Requirement: The "Audit status" option is activated on the segment under "Header properties".

Note

Overall status for check mode "None"

If the check mode "None" is set in the configuration of the audit data sources item, the "Audit status" field is always green.

- In the data table of the segment: Identifier of manipulations

Type of manipulation	Identifier in the data table
Value of entries changed	Directly at the entries
Entries added	
Entries deleted	The manipulated time range receives a start and end entry.

First, the data table shows the contents configured in the standard configuration for Audit. To output other contents, select or create a configuration.

Setting a display name for standard column

Introduction

You can assign a display name for the standard column of a data source item. When a display name is set, it is used in the data table instead of the default column title and is listed in the table header row.

Display names make reports clearer, for example, when data source items for contexts or tags have very long names.

You set the display name in the local configuration of the data source item.

Requirement

- The "WinCC Unified" tab is visible in Excel.
- There is a segment with a matching data source item.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Expand a segment by clicking on it.
   The area for adding and editing data source elements appears.
3. Move the mouse pointer to the data source item and click "Edit".
   The local configuration of the data source item opens.
4. Enter the desired column title in "Display name".
   The column title must be unique within the segment.

   Note

   Localization

   The column title is stored in the Runtime language currently set in the basic settings of the add-in.

   To localize the column title, change the Runtime language and repeat your entry in the new language.

5. Confirm your entry with "OK".

Result

- The data table uses the display name as the column title for the standard column of the data source item.
- As long as the following conditions are met, the "Display name" column is inserted into the table header row:
  - Display of the header row in table header row is enabled.
    Make this setting at the segment.
  - A display name is set for at least one data source item of the segment.

  The column lists the display names of all data source items. If no display name is set for a data source item, its cell remains empty.

Note

- If you assign a different configuration to the data source item, the display name is retained.
- To return to the display of the default column title after assigning a display name, enter the name of the data source item under "Display name".

Delete data source elements

Requirement

- The "WinCC Unified" tab is visible in Excel.
- A segment with a data source element is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Expand a segment by clicking on it.
   The area for adding and editing data source elements appears.
3. Move the mouse pointer over a data source element and click "Delete".

Working with configurations

Basics of configuration

The *configuration* of a data source item defines the values of a data source element that are displayed in a segment or how they are calculated and displayed.

There are specific configuration settings for each data-source-item type.

Data source items used in time series segments use a different configuration than data source items used in single-value segments.

You have the following options:

- Use standard configuration.
  There is a standard configuration for all types of data source items. Once added, data source items use the default configuration of their type.
  You can edit the standard configurations.
- Use user-defined configuration.
  You can create any number of user-defined configurations for all types of data source items.
  You can select one of the user-defined configurations on the data source item.
- Overwrite a configuration locally.
  You can overwrite the configuration selected at the data source item locally.

Creating or editing configurations for log alarms

Requirement

- The "WinCC Unified" tab is visible in Excel.

Creating a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click "New Configuration > Logging alarm configuration".
4. Enter the name of the configuration under "Configuration name".

5. (Optional) Enter texts or graphics from a text list or graphic list in the standard column instead of the alarm IDs.
   See Assigning text lists and graphic lists (Page 7708).
6. (Optional) Change the default settings of the optional columns. The optional columns are used to display the alarm properties.
   See Configuring optional columns (Page 7707).
7. (Optional) Filter the logging alarms to be displayed. You define a filter query for this purpose. The filter query can consist of up to two conditions.
   Proceed as follows:
   - Under "Filter", click "+" or "Add new condition row".
   - Select an alarm property, an operator, and enter a value.
   - Optional: Use "+" or "Add new condition row" to create additional conditions. Select whether the conditions are to be linked with a logical AND or OR.
8. Enable the option "Use system colors" so that the alarms are highlighted with the same colors as in the alarm control.
9. Confirm your entries with "OK".

Note

To not use the default column title for the standard column, set a display name in the local configuration of the data source item. See Setting a display name for standard column (Page 7711).

Editing a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click a configuration for logging alarms.
4. Edit the configuration settings. You have the same options as when creating the configuration.
5. Confirm your entries with "OK".

The changes are applied the next time you read in the Runtime data.

See also

Select configuration (Page 7705)

Calculation modes for data source elements (Page 7715)

Creating or editing configurations for an alarm statistics

Requirement

- The "WinCC Unified" tab is visible in Excel.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click "New Configuration > Alarm statistics configuration".
4. Enter the name of the configuration under "Configuration name".
5. (Optional) Enter texts or graphics from a text list or graphic list in the standard column instead of the alarm IDs.
   See Assigning text lists and graphic lists (Page 7708).
6. (Optional) Change the default settings of the optional columns. The optional columns are used to display the statistical calculations and alarm properties.
   See Configuring optional columns (Page 7707).
7. (Optional) Filter the contents to displayed in the alarm statistics. You define a filter query for this purpose. The filter query can consist of up to two conditions.
   Proceed as follows:
   - Under "Filter", click "+" or "Add new condition row".
   - Select an alarm property, an operator, and enter a value.
   - Optional: Use "+" or "Add new condition row" to create additional conditions. Select whether the conditions are to be linked with a logical AND or OR.
8. Enable the option "Use system colors" so that the alarms are highlighted with the same colors as in the alarm control.
9. Confirm your entries with "OK".

Note

To not use the default column title for the standard column, set a display name in the local configuration of the data source item.

See Setting a display name for standard column (Page 7711).

Editing a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click a configuration for alarm statistics.
4. Edit the configuration settings. You have the same options as when creating the configuration.
5. Confirm your entries with "OK".

The changes are applied the next time you read in the Runtime data.

See also

Adding alarm statistics (Page 7682)

Create or edit configurations for logging tags

Requirement

- The "WinCC Unified" tab is visible in Excel.

Creating a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

3. Click "New Configuration".
4. To create a configuration for logging tags in a time series segment, select the entry "Logging tag configuration".
   To create a configuration for logging tags in a single value segment, select the entry "Single value configuration logging tag".
5. Enter the name of the configuration under "Configuration name".
6. Under "Calculation mode", select the data to be written if no current value is available.
7. (Optional) If the configuration is for logging tags with the numeric data type, you can output texts or graphics from a text list or graphic list in the standard column instead of the tag value. See Assigning text lists and graphic lists (Page 7708).
8. Set the other settings as described below.
9. Confirm your entries with "OK".

Note

To not use the default column title for the standard column, set a display name in the local configuration of the data source item. See Setting a display name for standard column (Page 7711).

Editing a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click a configuration for logging tags.
4. Edit the configuration settings.
5. Confirm your entries with "OK".

The changes are applied the next time you read in the Runtime data.

Additional settings for time series segments

In time series segments, the following additional settings are available for logging tags:

Setting	Description
"Interval"	Only for the "Stepped" and "Interpolated" calculation modes.
"Columns" > "Quality Code"	(Optional) Change the default settings of the optional "Quality Code" column. See Configuring optional columns (Page 7707).

Additional settings for single value segments

In single value segments, the following additional settings are available for logging tags:

Setting	Description
"Time stamp"	Determine the date and time for which the value is read. Proceed as described below.
"Show captions"	Define whether a header is displayed in the columns for the time stamp, the data source item and the quality code.
"Show time stamp"	Determine whether and where this information is displayed in the table. The information is always in relation to the value cell.
"Show data source item"	
"Show quality code"	

To set the "Time stamp", select one of the following options:

	Absolute time information	Select a date and a time. The information is absolute.
	Relative time information	Select a reference time and a time interval. The information is relative to the current date.

	Read time information from cell	Applies the value of the cell currently highlighted in the Excel file. Make sure that the cell supplies a valid time.
	Read time information from tag	Applies the value of the set tag. Make sure that the tag supplies a valid time. Possible data types: • DateTime • String • Integer

Calculation modes for data source elements (Page 7715)

Creating or editing configurations for tags:

Requirement

- The "WinCC Unified" tab is visible in Excel.

Creating a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":
3. Click "New Configuration> Tag single value configuration".
4. Enter the name of the configuration under "Name".
5. (Optional) If the configuration is for tags with the numeric data type, you can output texts or graphics from a text list or graphic list in the standard column instead of the tag value. See Assigning text lists and graphic lists (Page 7708).
6. Set the other settings as described below.
7. Confirm your entries with "OK".

Note

To not use the default column title for the standard column, set a display name in the local configuration of the data source item. See Setting a display name for standard column (Page 7711).

Editing a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration".

3. Click a configuration for tags.
4. Edit the configuration settings.
5. Confirm your entries with "OK".

The changes are applied the next time you read in the Runtime data.

Settings for single value segments

In single value segments, the following settings are available for tags:

Setting	Description
"Show captions"	Select whether a header is displayed in the columns for the time stamp, the data source item and the quality code.
"Show time stamp"	Select whether the time stamp is output with the value.
"Show data source item"	Select whether the quality code is output with the value.
"Show quality code"	Select whether the quality code is output with the value.

Creating or editing configurations for contexts

Requirement

- The "WinCC Unified" tab is visible in Excel.

Core statement

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click "New Configuration".
4. Select the entry "Configuration context".
5. Enter the name of the configuration under "Configuration name".
6. (Optional) Change the default settings of the optional columns. The optional columns are used to display important contextual information.
   See Configuring optional columns (Page 7707).
7. Confirm your entries with "OK".

Note

To not use the default column title for the standard column, set a display name in the local configuration of the data source item. See Setting a display name for standard column (Page 7711).

Editing a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click a configuration for contexts.
4. Edit the configuration settings.
5. Confirm your entries with "OK".

The changes are applied the next time you read in the Runtime data.

Creating and editing configurations for user-defined columns

Requirement

- The "WinCC Unified" tab is visible in Excel.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click "New Configuration > User-defined column configuration".
4. Enter the name of the configuration under "Configuration name".

5. Under "Formula", select one of the following options:
   - Enter a fixed string.
     The string is transferred into each cell of the column.
   - Enter an Excel formula.
     The formula is copied into each cell of the user-defined column and adapted to the respective row.
     To prevent a part of the formula from being adjusted, place the character "$" in front of it.
     Example

Formula in configuration		=B2+C2	=B$2+C2
Adapting the formula in the report	in line 2	=B2+C2	=B2+C2
	in line 3	=B3+C3	=B2+C3
	in line 4	=B4+C4	=B2+C4

Note

No validity check

The formula is not tested for correctness during either input or dynamic adaptation.

6. Confirm your entries with "OK".

Adding or editing configurations for audit

Introduction

Check mode

The check mode of the configuration of an audit data source item determines

- Whether an integrity check is performed when the Runtime data is read, and what is checked. You can output the overall result of the check in the table header row in the "Audit status" field.
- Which audit data records are provided in the data table.

Possible check modes:

"None"	Provides the data for all audit data records that fall within the requested time range. No integrity check is performed. Default setting
"Check only"	Checks all audit data records that fall within the requested time range without providing their data. It is tested whether data records have been manipulated, deleted or added.
"Check entries"	Check the audit data records and provides their data that fall within the queried time range and that have not been deleted from the Audit Trail or subsequently added. It is checked whether data records have been manipulated.
"Check all"	Checks all audit data records and provides their data that fall within the queried time range. It is tested whether data records were manipulated, deleted from the audit trail or subsequently added.

Filter type

An Audit data record consists of two entries:

- An entry for the user expectation
- An entry for the system response.

User expectation and system response may differ. In addition, there are situations in which only one of the two data records is created.

The filter type controls which data records and which entries are included in the report.

Possible filter types:

Filter type	User expectation equals system response	User expectation does not equal system response	Data record entry for user expectation or system response is missing
"Show all data in detail"	Both data record entries are inserted.		The existing data record entry is inserted.
"Show data and conformity errors"	The data record entry with the user expectation is inserted.	Both data record entries are inserted.	
"Show only data with conformity errors"	No data record entry inserted.		

Requirement

- The "WinCC Unified" tab is visible in Excel.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   

3. Click "New Configuration > Audit configuration".
4. Enter the name of the configuration under "Name".
5. Select a check mode:
6. Specify a filter type.
   Preset value: "Show data and conformity errors"
7. (Optional) Change the default settings of the optional columns. The optional columns are used to display the audit attributes.
   See Configuring optional columns (Page 7707).

8. (Optional) To further filter the inserted content, define a filter query.
   The filter query can consist of up to two conditions. Proceed as follows:
   - Under "Filter", click "+" or "Add new condition row".
   - Select an Audit attribute, an operator and enter the value of the attribute.
   - Optional: Use "+" or "Add new condition row" to create additional conditions. Select whether the conditions are to be linked with a logical AND or OR.
9. Confirm your entries with "OK".

Note

To not use the default column title for the standard column, set a display name in the local configuration of the data source item. See Setting a display name for standard column (Page 7711).

Editing a configuration

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration":

   
3. Click a configuration for Audit.
4. Edit the configuration settings. You have the same options as when creating the configuration.
5. Confirm your entries with "OK".

The changes are applied the next time you read in the Runtime data.

Examples of the configuration of the filter type

The following table contains examples of data records that were generated in Runtime through changes to tags monitored by Audit:

Data record ID	Tag name	Modified by	Old value	New value	Description
1A	Motor1_Speed	User1	0	10	An operator changes the speed of a motor in an I/O field of an HMI screen.
1B	Motor1_Speed	System	0	10	User expectation and system response are identical.
2A	ValvePercentile	User1	0	100	An operator opens a valve using a slider on an HMI screen. The valve has a physical blockage and cannot be opened. Therefore, no data record entry for the system response is generated.

Data record ID	Tag name	Modified by	Old value	New value	Description
3A	ValvePercen-tile	User1	0	99	A physical block has been removed and the operator repeats the entry. The valve reacts, but cannot be fully opened. User expectation and system response differ.
3B	ValvePercen-tile	System	0	49	
4B	Mo-tor2_Speed	System	0	20	An operator changed the speed of another motor. The resulting data record was manipulated, and the user expectation entry was deleted. There is only one entry for the system response.

The following table shows which data record entries are inserted into the data table depending on the filter type selected when generating the report:

Data record ID	Tag name	Modified by	Old value	New value
Filter type "Show all data in detail"				
1A	Motor1_Speed	User1	0	10
1B	Motor1_Speed	System	0	10
2A	ValvePercentile	User1	0	100
3A	ValvePercentile	User1	0	99
3B	ValvePercentile	System	0	49
4B	Motor2_Speed	System	0	20
Filter type "Show data and conformity errors"				
1A	Motor1_Speed	User1	0	10
2A	ValvePercentile	User1	0	100
3A	ValvePercentile	User1	0	99
3B	ValvePercentile	System	0	49
4B	Motor2_Speed	System	0	20
Filter type "Show only data with conformity errors"				
2A	ValvePercentile	User1	0	100
3A	ValvePercentile	User1	0	99
3B	ValvePercentile	System	0	49
4B	Motor2_Speed	System	0	20

Select configuration

Requirement

- The "WinCC Unified" tab is visible in Excel.
- A segment with a data source item is available.
- There is a user-defined configuration for the type of the data source item.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Select the segment.
   The segment is extended by the area for the data source items.
3. Select the desired configuration from a data source item in the drop-down list.
4. Click "OK".

Result

The changes are applied the next time you read in the runtime data.

Overwrite a configuration locally

A local configuration overwrites the configuration selected at the data source item. It applies only to the data source item for which it was entered.

Requirement

- The "WinCC Unified" tab is visible in Excel.
- A segment with a data source item is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Select the segment.
   The segment is expanded to include the plant complex for the data source items.
3. Move the mouse over a data source item and click "Edit".
   You create a local configuration that first adopts the values of the original configuration.
4. Enter a name for the local configuration.
5. (Optional) Set a display name. See Setting a display name for standard column (Page 7711).
6. Make the remaining settings as required.
   You can make the same settings as in the default and custom configurations.
7. Confirm your entries with "OK".

Result

The changes are applied the next time you read in the Runtime data.

Delete configuration

Requirement

A configuration is available.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click "Data source item configuration".
3. Move the mouse to a configuration.

   Note
   Default configurations cannot be deleted

   You can edit default configurations but not delete them.

4. Click "Delete".

Result

- The configuration is deleted.
- Data source items with this configuration obtain a local configuration with the same settings.

Configuring optional columns

Introduction

In time series segments, data source items of the following types have optional columns:

- Logging tag
- Logging alarm
- Alarm statistics
- Audit
- Context

The optional columns of a data source item depend on its type. The configuration of the data source items controls whether and how the data table shows these columns.

This section describes how to configure the optional columns.

Requirements

The data source item configuration is open. The configuration must apply to a time series segment.

Showing and hiding columns

1. To show an optional column in the data table, enable the option for the desired column in the "Columns" area.
2. To hide a column, disable its option.

Changing the column title

The data table uses as default column titles the identifiers you see in the "Columns" area. To change the default column titles, do the following.

1. In the "Columns" area, move the mouse pointer to an optional column.
2. Click the button with the pin.
3. Assign a unique column title.

Note

Localization

The column title is stored in the Runtime language currently set in the basic settings of the add-in.

To localize the column title, change the Runtime language and repeat your entry in the new language.

Changing the column sequence

To change the order of the optional columns in the data table, proceed as described in Changing the column sequence (Page 7712).

Assigning text list or graphic list

The values of numeric columns can be replaced by texts or graphics when the Runtime data is read in.

To assign a suitable text list or graphic list to the property, proceed as described in Assigning text lists and graphic lists (Page 7708).

Assigning text lists and graphic lists

Introduction

If standard columns and optional columns of data source items output numerical values, you can assign text lists and graphic lists to these columns. When the Runtime data is read in, the cell values of these columns are replaced by texts or graphics from the assigned lists.

This function improves the readability of the report and helps to draw the reader's attention to important information.

Note

Restrictions

- Tags/logging tags
  Assign a text list or graphic list to the standard column of data source items with a Tag or Logging tag type only if the tag or logging tag has a numeric data type.
  You can assign a text list or graphic list to the optional "Quality Code" column regardless of the data type of the tag.
- User-defined columns
  It is not possible to assign a text list or graphic list for data source items with the User-defined column type.
- Context and audit
  Usually, the names of context objects and audit objects displayed in the standard column do not contain purely numerical values. It is not recommended to assign a text list or graphic list.

Example

Add two data source items with the same logging tag to a time series segment.

For the first data source item, use the default configuration. This causes the report to output the tag value in the standard column.

For the second data source item, select a configuration in which a graphic list is assigned to the standard column. The graphic list contains representational graphics staggered by value range. As a result, the report outputs a graphic in the standard column.

After reading in the Runtime data, the standard column of the second data source item makes readers of the report aware of limit violations. Readers can get the exact tag value from the standard column of the first data source item.

Requirements

- A segment with a data source item was created in the add-in.
- Suitable text lists or graphic lists have been configured in engineering for the connected data source.

Assigning text lists and graphic lists to the standard column

1. Click on "Segments" in the "Configuration" group.
2. Select the segment.
   The data source items of the segment are displayed.
3. Move the mouse over a data source item and click "Edit".
   The local configuration of the data source item opens.

4. Select a suitable list under "Assign text/graphic list".
5. To preview the selected list and its graphics or texts, click the "i" button.
   To hide the preview, click the "i" button again.

Assigning optional columns to text lists and graphic lists

1. Click on "Segments" in the "Configuration" group.
2. Select one of the following options:
   To make the assignment apply to a specific data source item, follow these steps:
   - Select the segment.
     The data source items of the segment are displayed.
   - Move the mouse over the data source item and click "Edit".
     The local configuration of the data source item opens.

   To make the assignment apply to multiple data source items of the same type, follow these steps:
   - Click "Data source item configuration": 
     You can see all default and custom configurations.
   - Click on the desired configuration.
     The configuration opens.
3. In the "Columns" area, click the following button next to the desired optional column:

   

   An interface for assigning a text list or graphic list is loaded into the add-in.
4. Select the desired graphic list or text list from the drop-down list.
5. To preview the selected list and its graphics or texts, click the "i" button.
   To hide the preview, click the "i" button again.

   Note

   If you are connected offline to the data source, no preview of graphic lists is available.

6. Confirm your entries.

Result

When the Runtime data is read in, the assigned lists are searched for an entry that matches the actual cell value:

- If a matching entry is found, the corresponding text or graphic is inserted into the data table.
- If no matching entry is found, the actual cell value is inserted.

Note

The assignment of graphic lists slows down the import of the Runtime data into the Excel add-in.

Basic information on segments (Page 7670)

Setting a display name for standard column

Introduction

You can assign a display name for the standard column of a data source item. When a display name is set, it is used in the data table instead of the default column title and is listed in the table header row.

Display names make reports clearer, for example, when data source items for contexts or tags have very long names.

You set the display name in the local configuration of the data source item.

Requirement

- The "WinCC Unified" tab is visible in Excel.
- There is a segment with a matching data source item.

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Expand a segment by clicking on it.
   The area for adding and editing data source elements appears.
3. Move the mouse pointer to the data source item and click "Edit".
   The local configuration of the data source item opens.
4. Enter the desired column title in "Display name".
   The column title must be unique within the segment.

   Note

   Localization

   The column title is stored in the Runtime language currently set in the basic settings of the add-in.

   To localize the column title, change the Runtime language and repeat your entry in the new language.

5. Confirm your entry with "OK".

Result

- The data table uses the display name as the column title for the standard column of the data source item.
- As long as the following conditions are met, the "Display name" column is inserted into the table header row:
  - Display of the header row in table header row is enabled.
    Make this setting at the segment.
  - A display name is set for at least one data source item of the segment.

  The column lists the display names of all data source items. If no display name is set for a data source item, its cell remains empty.

Note

- If you assign a different configuration to the data source item, the display name is retained.
- To return to the display of the default column title after assigning a display name, enter the name of the data source item under "Display name".

Standard column (Page 7672)

Overwrite a configuration locally (Page 7706)

Changing the column sequence

Introduction

For a time series segment, you can change the default column order of the data table.

You have the following options:

- Specify the order which the data source items have in the data table.
- For each data source item: Set the order of its optional columns.

Note

The time stamp column always appears first.

Requirement

- The "WinCC Unified" tab is visible in Excel.
- A time series segment has been created.

Change the order of data source items

Procedure

1. Click on "Segments" in the "Configuration" group.
2. Click the time series segment in the list of time series segments.
   The data source items of the segment are displayed.
3. Left-click a data source item and move it up or down using drag-and-drop operation.

Result

The order of data source items in the segment interface is changed.

The next time the Runtime data is read in, the data table outputs the data source items in this order.

Changing the order of optional columns

Procedure

1. Select one of the following options:
   To change the column order of a particular data source item, follow these steps:
   - Select the segment.
     The data source items of the segment are displayed.
   - Move the mouse over the data source item and click "Edit".
     The local configuration of the data source item opens.

   To change the column order for all data source items that use the same configuration, follow these steps:
   - Click "Data source item configuration":

     

     You can see all default and custom configurations.
   - Click on the desired configuration.
     The configuration opens.
2. Move the mouse pointer to a column under "Columns".
   The columns you see depend on the type of data source item.
3. Move the column up or down using the arrow buttons or drag-and-drop.

Result

The order of the optional columns in the configuration is changed.

The next time the Runtime data is read in, the data table outputs the optional columns in the changed order.

Basic information on segments (Page 7670)

Configuring optional columns (Page 7707)

Reading Runtime data in Excel

Note

Reading in Runtime data in Excel is used for testing. It is not intended for mass retrieval of data, as is the case when report jobs are executed in Runtime.

Requirement

An online connection is established.

Reading in all segments

1. Select "WinCC Unified > Segments".
2. Click "Update all":

Reading in individual segments

1. Select "WinCC Unified > Segments".
2. Next to a segment in the list of segments click, "Update":

Result

The segment or segments are run. The Runtime data of your data source items are read into Excel.

Note

Controlling the column width and row height

When the automatic adjustment of the column width and row height is disabled in the segment properties, the text read in may be truncated or the formula results are replaced with "#" characters.

Check the column widths and row heights and adjust them manually, if required, or select automatic adjustment. Manual adaptations only apply in the Excel add-in. They are not included in the generated reports.

Note

Removing Runtime data from report template

Remove the Runtime data from the report template before you save the report template and make it available for uploading to Runtime.

To do this, click the "Delete Runtime data" button  in the toolbar of the Excel add-in.

Diagnostics during the data query

Successful execution of the data query is documented by the add-in with a status message in the table.

If an error occurs during the data query, a general error message is displayed under status. In addition, detailed error messages are displayed in the "ErrorLog" worksheet.

Calculation modes for data source elements

If there is no current value for a data source item for a requested point in time, the following calculation modes are available.

Calculation modes for tags

The following calculation modes are available for tags of a time series segment:

Calculation mode	Description
Raw	The actual value available for the specified period. If no data are available, no value is output.
Stepped	If no data are available, the last value is used. With this mode you can also use values with an invalid quality code.
Interpolate	The values are interpolated linearly for the specified time period. With this mode you can only use values with a valid quality code.

The following calculation modes are available for tags of a single value segment:

Calculation mode	Description
Interpolate	The values are interpolated linearly for the specified time period. With this mode you can only use values with a valid quality code.
Left	If no data is available, the last value before the specified period is used.
Right	If no data is available, the last value after the specified period is used.

Create or edit configurations for logging tags (Page 7697)

19.2.4.5 Making general settings

Changing the language

Changing the add-in language

The Excel add-in automatically uses the same user interface language as Excel. If you are using a language for Excel that is not included in the Unified options, English is used as the default language.

You can select the language for the contents of the report independently of the interface. To select another language, the language must be configured in Runtime.

Selecting the language for the report

1. Select "WinCC Unified > Segments".
2. Click "Basic settings":

   

3. Under "Runtime language", select the language of the report content.
4. Under "Query language" you select which language data queries have that require user input, e.g. filter definitions.

Adapting the work area

Undocking and moving the add-in

To enlarge your working area, you can undock the Excel add-in:

1. Open the drop-down list in the header of the add-in.
2. Click "Move".
3. Move the mouse pointer to the desired location and click the left mouse button.

4. To move the add-in again, keep the left mouse button pressed in the header of the add-in and move the mouse.
5. To dock the add-in again, double-click in the header of the add-in.

Adapting the size of the add-in

1. Open the drop-down list in the header of the add-in.
2. Click "Resize".
3. Move the mouse pointer to the left to make the add-in wider or to the right to make it narrower.
4. Left-click when you have reached the desired size.

Zooming in the add-in

Procedure

To zoom in or out of the display in the add-in, press <CTRL> and move the mouse wheel.

19.2.4.6 Undo and redo

The Excel functions "Undo" and "Redo" are not available in the add-in.

19.2.4.7 Tips on design and layout

This section includes tips on the visual design of reports. The apply for:

- Report templates
- Reports that were generated as XLSX file

Note

Deviating PDF results

A PDF report created by LibreOffice can deviate in content or layout from a PDF report generated with Excel, for example, if the report template uses common Excel features that LibreOffice does not support, such as special fonts or chart types.

Arranging segments

Always place the segments of a report template side by side or each in their own worksheet.

Because the data tables of the segments grow dynamically, tables can overlap when segments are placed one below the other. In the add-in, this causes an error of the OfficeExtension.Error class when reading in the Runtime data.

Changing the column sequence

See section Changing the column sequence (Page 7712).

Adapt column width and row height

For each segment of a report template, check whether the column widths and row heights of your data table are wide or high enough for the values to be read. If this is not the case, texts in the generated report are truncated or the formula results are replaced with "#" characters.

To do this, select one of the following options:

- In the properties of the segments, select the options for automatic adjustment of the column width and row height.
- Click "Update all" in the report template.
  Values are imported to Excel from the data source. Check the column widths and row heights and adjust them manually, if required.

  Note

  The manual adaptations apply only in the Excel add-in. They are not included in the generated reports.

Replacing numerical values

If columns of a data source item output numeric values, you can assign text lists and graphic lists to the columns. When the Runtime data is read in, the cell values of these columns are replaced by texts or graphics from the assigned lists. This improves the readability of the report and helps to draw the reader's attention to important information.

Example: Visualizing limit violations of tags with graphics

See section Assigning text lists and graphic lists (Page 7708).

Preparing imported Runtime data

Adjust the cell formatting of the Runtime data, for example, font, color, alignment, or number format. The rows inserted when reading the Runtime data adopt the formatting.

Add diagrams, pivot tables or formulas that graphically visualize, structure or evaluate the data imported from Runtime.

Note

If you have read Runtime data into the report template for better data preparation, remove it before saving the report template and making it available for upload to Runtime.

To do this, click the "Delete Runtime data" button in the toolbar of the Excel add-in.

Set up page

Use "File > Print > Set up page" to define details for printing the report, for example:

- Alignment of the report (portrait format or landscape format)
- Scaling, for example, to print all columns on one page
- Inserting a user-defined header or footer

The print settings set in the report template are applied in Runtime when a report job is executed for PDF generation.

Renaming worksheets and segments

When you add a segment to a report template in the add-in, a table is created in Excel. The add-in addresses the table by the name of the worksheet and segment.

Do not rename worksheets after adding segments.

Do not change the table name of a segment using the Excel property "Table name". Edit the segment in the add-in and rename it there.

19.2.5 Working with production reports in Runtime

19.2.5.1 Workflow for working with reports in Runtime

Introduction

The following workflow describes which works are required in the "Reports" control so that production reports are generated in Runtime.

The reports can be stored as file in the file system and sent as an attachment to an e-mail. Alternatively, an e-mail without attachment can also be sent about the generation of the report. In this way, employees from management and production can be informed about the production situation promptly, regardless of their location.

You can send the e-mail using a secure SMTP server (authentication with user name and password or via certificate) or an unsecured SMTP server, for example, an internal company mail server.

Requirement

- Requirements in TIA Portal:
  - The necessary project data were configured for the HMI device for which reports are to be created.
  - The "Reports" control was placed on an HMI screen of the device.
  - The "Enable Reporting" option was enabled in the Runtime settings of the device.
  - (Optional) The storage locations for reports and the Reporting database were configured in the Runtime settings of the device.
- The HMI device has been compiled, uploaded to the Runtime server and its project is running.
- When using contexts: Contexts have been defined and executed in Runtime for the project.
- The Runtime server has access to report templates.
- For cross-project and cross-Runtime use of report templates: The data sources used in the report template can also be found on the HMI device. Make sure that the names and plant hierarchy are consistent.

Procedure

1. To send reports by e-mail, configure the global e-mail settings:
   - When one of the servers requires a certificate for sending e-mails, upload the certificate.
   - Create contacts for the e-mail receivers and e-mail senders.
   - Create the required SMTP server configurations.
2. Configure job parameters for report templates, triggers and targets.
   These job parameters will then be available to you for selection when configuring the report jobs.
3. Configure report jobs.
   Reports are generated in Runtime when the report jobs are executed.
4. (Optional) Perform report orders manually.
5. In the control, get an overview of which reports have been generated.
6. Download the reports, if necessary.
7. (Optional) To reuse the configuration of the "Reports" control, such as on a device in another network, transfer the existing configuration from the control from one device to the control of the other device.

Configuring job parameters

First, you configure which job parameters are available for selection during the configuration of the report jobs. You configure the following job parameters:

- The available report templates
  The report template defines which data the report outputs. Import and/or delete templates, if required.
- The available triggers
  The trigger defines when a report job is executed. Add triggers, edit triggers or delete them.
- The available targets
  Targets define whether reports are made available to users in the file system or via e-mails. Add targets, edit triggers, or delete them.

You set further job parameters while configuring a report job in the "Report jobs" tab.

Configuring a report job

You configure the following for each report job:

- Name of the report job
- Used report template
- Name of the reports generated by this template

Note

Texts through dynamic placeholders

Placeholders are available to you when defining the report name. The placeholders are evaluated and replaced by text during execution of the report.

See also Dynamic placeholder (Page 7746).

- Targets of the generated report
  To send e-mails, select a target of the type "E-mail".
- Per target: The target format of the generated report
  Possible formats: .XLSX and .PDF
- Trigger
- Comment
- Activate

19.2.5.2 The user interface of the "Reports" control

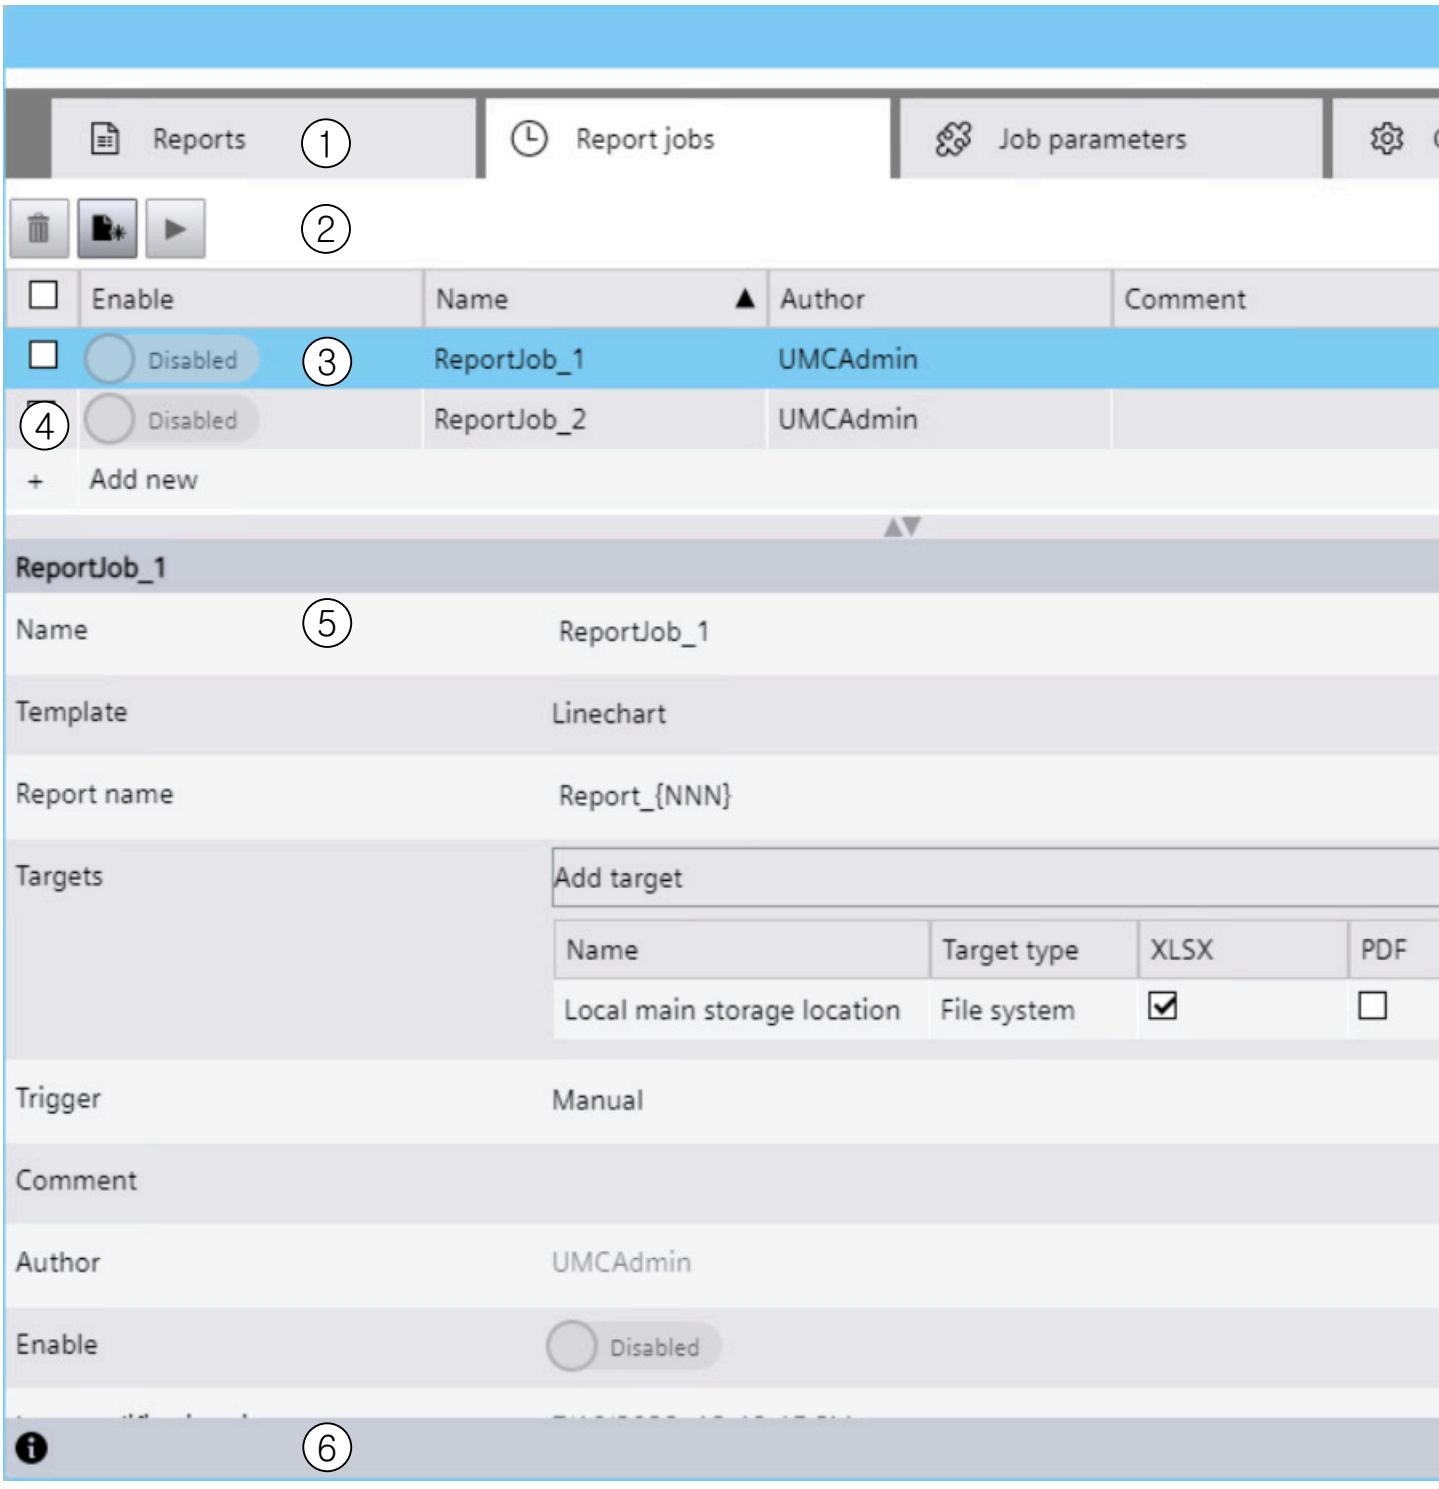
Note
Automatic data transfer

Changes in the "Reports" control are saved automatically.

Layout

You create and manage report jobs in the "Reports" control. You also have access to the reports generated by the report jobs.

The control has the following structure:



1 Tab for the configuration and management of reports, report jobs, job parameters and global settings

2 Toolbar
The buttons you see depend on the tab.

3 Work area
On the "Reports", "Report jobs" and "Job parameters" tabs: List of elements available on the tab
On the "Global settings" tab: The settings

4 Options for selecting the elements
You can select elements individually or all at once.

5 Detail area
Shows the properties of the selected element.

6 Information bar

Tab

"Reports" tab

Here you can see which reports have been generated. You can download or delete reports via the toolbar.

The "Status" column shows Information:

- On the status of the generated report files (XLSX and PDF)
- On the status of the targets (File system and E-mail)

Overview of the status icons:

Status	Description
	Execution has been successfully completed.
	An error occurred during execution.
	Execution is in progress.

A click on an icon opens a detailed status message.

"Report jobs" tab

Here you create new report jobs, manage existing report jobs or start a report job manually.

"Job parameters" tab

Here you manage the parameters with which you configure the report jobs in the "Report jobs" tab.

"Global settings" tab

Here you make the following settings:

- For sending e-mails
- For transfer of the control configuration
- For creating an offline configuration file
- For configuring paging

Toolbar

The following buttons are available in the toolbars of the tab:

Icon	Button	
	Delete	Deletes the elements whose option is enabled in the work area.
	• Add new • Import	• Creates a new element. • "Job parameters > Templates" tab: To import a report template into Runtime
	Run	In the "Report jobs" tab. Manually creates a report for the report job whose option is enabled in the work area.
	Export	• In the "Job parameters > Templates" tab: To export report templates • In the "Reports" tab: To download reports to the client

Information bar

The button in the information bar displays general information sent by the reporting service, for example, on whether a report job has been executed.

19.2.5.3 Setting global email settings

If configured accordingly, an e-mail is sent automatically after a report job is executed. The e-mail can include the report as an attachment.

Maintenance of the basic settings for sending e-mails is carried out in the "Global settings" tab:

- If necessary: The certificates that the e-mail sender uses to authenticate itself at the SMTP servers.
- The contact information of the e-mail senders and e-mail receivers.
- The configuration of the SMTP server via which the e-mails are sent.

Upload certificates

Store the certificates of the SMTP servers that require authentication via certificate.

Requirement

- You have access to the storage location of a valid certificate file.

Procedure

1. In the "Reports" control, click on the "Global settings > Certificates" tab.
2. Click "Add new" in the toolbar.
   Alternative: In the work area, click "Add new".
3. In the dialog that opens, select the certificate file.
4. Confirm your input.
5. Optional: Select the uploaded certificate in the work area and enter a comment on the certificate in the detail area.

Result

The certificates uploaded here are available in the "Contacts" tab.

Maintaining contacts

Store the data of the e-mail senders and email recipients.

Procedure

To create a new contact, follow these steps:

1. In the "Reports" control, click on the "Global settings > Contacts" tab.
2. Click "Add new".
3. Enter the name of the contact.
4. Enter the e-mail address of the contact.
5. To use the contact as a sender for an SMTP server that requires authentication with a certificate, select the appropriate certificate under "Certificate".
6. To use the contact as a sender for an SMTP server that requires authentication with a user name and password, enter the password.
   The e-mail address is used as the user name.
7. (Optional) Enter a comment relating to the contact.

Result

The contacts configured here are available:

- As the e-mail sender in the SMTP server configuration.
- As an e-mail recipient when configuring "target" job parameters with the target type e-mail

Maintenance of the SMTP server configuration

Store the data of the SMTP servers via which the e-mails are sent.

Requirement

Contacts that are suitable as senders have been entered in the "Global Settings > Contacts" tab.

Procedure

To create a new SMTP server configuration, follow these steps:

1. In the "Reports" control, click on the "Global settings > SMTP" tab.
2. Click "Add new".
3. Specify the following:

Field	Description
"Name"	Enter the name of the SMTP server configuration.
"Address"	Enter the URL of the SMTP server. Servers without authentication (e.g. company-internal mail servers) and with authentication are permitted. Example: URL of a company mail server: `mail.<Company name>.com`
"Port"	Enter the port number of the SMTP server. Default setting: 25
"Sender"	In the list, select the contact that is used as the sender for this SMTP server configuration. All contacts maintained under "Contacts" are offered to you for selection. Select a sender that meets the respective requirements of the server.
"Comment"	(Optional) Enter a comment relating to the SMTP server configuration.

Result

The servers configured here are available when configuring the "Target" job parameters with the target type email.

19.2.5.4 Configuring task parameters

Job parameters define the details of a report job.

You configure the following parameters on the "Job parameters" tab:

- Templates
- Trigger
  Define trigger when a report job is executed.
- Targets
  Targets define how a report is made available to users. The following target types are available:
  - "E-mail"
    An e-mail is sent after a report job is executed. The report generated by the report job can be included with the e-mail as an attachment.
  - "File system"
    The reports generated by the report job are stored in the file system.

The parameters configured here are available to you for selection when configuring the report jobs in the "Report jobs" tab.

You define the remaining job parameters while configuring a report job in the "Report jobs" tab.

Importing and exporting report templates (Page 7728)

Deleting templates (Page 7729)

Configure trigger (Page 7729)

Importing and exporting report templates

Requirement

- The "Reports" control is placed on a screen of the project.
- The "Job parameters > Templates" tab is visible in the control.
- Import: You have access to the storage location of the report template.
- Export: Report templates have been imported into the control.

Importing report template

1. Click "Add new" in the toolbar.
   Alternative: In the work area, click "Add new".
2. In the dialog that opens, select the file of a report template.

3. Confirm your input.

Note

No validation

The template is not validated during import.

4. Optional: In the work area, select the imported report template in the work area and enter a comment describing the template in the detail area.

Exporting report templates

1. In the work area, select the options next to the report templates you want to export.
2. Click "Export" in the toolbar.

The report templates are downloaded to the download folder or a user-defined directory according to the device settings.

Deleting templates

Requirement

- The "Reports" control is placed on a screen of the project.
- The "Job parameters > Templates" tab is visible in the control.
- Templates have been imported into the control.

Procedure

1. In the work area, select the options next to the templates you want to delete.
2. Click "Delete" in the toolbar.

Deleting used templates

The "In use" column shows whether the template is used by a report job.

If you delete a template that is used by a report job, the report job is marked as inconsistent and no longer executed.

Configure trigger

Introduction

In the "Job Parameters > Triggers" tab you configure which automatic triggers are available for selection when configuring report jobs.

Report jobs with automatic triggers are executed if the report jobs on the "Report jobs" tab are set to active and their trigger event occurs. Users can also start the execution manually.

Requirement

- The "Reports" control is placed on a screen of the project.
- The "Job parameters > Trigger" tab is visible in the control.
- To use the trigger type "Context trigger": Contexts are available in the project.

Add trigger

1. In the work area of the tab, click "Add new".
   A new trigger is created and displayed in the detail area.
2. Assign a unique name to the trigger.
3. Select the trigger mode:

Trigger type	Triggering the trigger
"Tag trigger"	Automatically when the configured value condition occurs at the tag defined in the trigger.
"Serial trigger"	Automatically within the user-defined interval when the time defined by the series has been reached.
"Context trigger"	Automatically when the selected context is started or stopped. Optional: By using a condition, you can also limit the triggering of the trigger to specific context values.

4. Depending on the selected trigger type, set the settings for the new trigger as described below.
5. Optional: Enter a comment for the trigger.

Settings for tag trigger

1. Click "Select tag".
2. Click "Load".
3. Select the required tag and click "OK".
4. Set the condition and the condition value.
   Example:

Set tag	<tag name>
Condition	>
Condition value	100

The trigger will be initiated when the tag receives a value greater than 100.

Settings for serial triggers

1. Select the serial pattern.
   The series pattern defines the occurrence and time at which the trigger is initiated.
   Example: Weekly > Every 2 weeks > Fridays
2. Select the series area.
   The series range defines the period in which the trigger is initiated.

"Start"	Specify the start date
"Time"	Specify the time at which the trigger is initiated.
"End on"	Specify the end date. The trigger will be executed for the last time on this day.
"End after"	Determine the number of dates after which the series ends.
"No end date"	The series runs indefinitely.

Settings for context triggers

1. Click "Select context".
2. In the "Context selection" dialog, click "Select plant object".
3. In the "Browser view" dialog, select a plant object and confirm your input.
   In the "Context selection" dialog you can see all contexts that have been defined for the selected plant object.
4. Select a context and confirm your input.
5. Under "Context status", select when the trigger will be triggered:

"Started"	When starting the context.
"Stopped"	When stopping the context.

6. Optional: To bind the execution of the report order to certain context values, you define a condition:

"Condition"	Select an operator.
"Value"	Select a context value.

Example:

Plant object	"MyPlant.hierarchy::PlantView/Bottling"
Context	"Product"
Context state	"Started"
Condition	=
Value	"Orange lemonade"

Report jobs with this trigger are always executed when the context "Product" defined on the plant object "Bottling" is started with the value "Orange lemonade".

Delete trigger

Select the option of the desired trigger in the work area of the "Job Parameters > Triggers" tab and click "Delete" in the toolbar.

Edit trigger

1. Enable the option of the desired trigger in the work area of the tab.
2. In the detail area, edit the settings of the trigger.

Note
No change of the trigger type

The trigger type can only be set when adding the trigger.

Add target with target type "E-mail"

Requirement

- The "Reports" control is placed on a screen of the project.
- The receivers of the e-mails are maintained as contacts in the "Global settings > Contacts" tab.
- An SMTP server, with which the e-mail is to be sent, has been configured in the "Global settings > SMTP" tab.

Procedure

1. In the "Reports" control, click on the "Job parameters > Targets" tab.
2. In the work area of the tab, click "Add new".
3. Select "E-mail" as target type.
   A new target is created and displayed in the detail area.
4. Assign a unique name to the target.
5. Select an SMTP server configuration.
6. Add the desired receivers and CC receivers:
   – To do so, select a contact from the list "Add receiver" or "Add CC receiver".
   – Add the contact by clicking "+".
7. Enter the e-mail subject.
   To integrate the report name into the subject line, use the placeholder {ReportName}.
8. Enter the e-mail text.
   To integrate the report name into the email text, use the placeholder {ReportName}.
9. (Optional) Enter a comment.

Result

The target is available for selection when configuring report jobs.

An e-mail is sent after a report job is executed with this target. The e-mail can include the report as attachment.

See also

Dynamic placeholder (Page 7746)

Add a target with "File system" target type

Introduction

A reporting job with a target of the "File system" target type saves reports to a file system.

When configuring the report jobs, you can choose from pre-configured and user-defined targets of this target type.

Preconfigured targets

The following targets with "File system" target type are pre-configured:

Local project storage location	The reports are stored in the following folder: `<Project folder of the Runtime project>\Reports`
Local main storage location	The reports are stored in the local main storage location for reports. The local main storage location is configured in TIA Portal in the Runtime settings of the HMI device. If this setting has not been set in TIA Portal, the reports are stored as follows: • Unified PC: In the folder configured during installation of Runtime or later in the "WinCC Unified Configuration" tool • Unified Comfort Panel: In the "Reports" folder on the SD card inserted in the Panel: `media/simatic/X51/Reports`

You can select these targets in the "Report jobs" tab. You cannot edit or delete these targets in the "Job parameters > Targets" tab.

User-defined targets

In the "Reports" control, you can create user-defined targets of the "File system" target type. These user-defined targets are always subfolders of the local main storage location.

Requirement

- The "Reports" control is placed on a screen of the project.
- Unified Comfort Panel: The panel contains the storage media configured in the TIA Portal Runtime settings as storage locations for reports and for the reporting database.

Procedure

To add user-defined targets of the "File system" target type, follow these steps:

1. In the "Reports" control, click on the "Job parameters > Targets" tab.
2. In the work area of the tab, click "Add new".

3. Select "File system" as target type.
   A new target is created and displayed in the detail area.
   Under "Destination path", you can see the path to the local main storage location for reports.
4. Assign a unique name to the target.
5. Under "Subfolder", enter the path to the subfolder in which the report is to be saved.
   Use the following notation: <folder name> or <folder name>\<folder name>\...

   Note
   Relative path information

   The path specification is relative to the local main storage location for reports.

6. (Optional) Enter a comment.

Result

The target is available for selection when configuring report jobs.

When a report job with this target is being executed, the generated report is stored in the subfolder of the local main storage location defined as the target. If the folder entered under "Target path" does not exist, it is created by the system.

Note
Change of the local main storage location for reports

When the local main storage location for reports changes, the targets are automatically adapted. New reports are stored relative to the new local main storage location. The old folders are not deleted.

19.2.5.5 Configuring report tasks

Creating a report job

Introduction

A *report job* is a job for generating reports in Runtime. The configuration of a report job controls the details of the generation.

Requirement

- The "Reports" control is configured on a screen of the project.
- The following job parameters were configured in the control:
  - At least one template has been imported.
  - To automatically execute a report job: Triggers are configured in the "Job parameters > Trigger" tab.

- For sending an email after execution of the report job:
  - Email contacts were configured in the global settings.
  - An SMTP server was configured in the global settings.
  - A target of the target type "E-mail" was configured in the "Job parameters > Targets" tab.
- For a report job with the target format PDF:
  - Microsoft Office Excel or LibreOffice is installed on the runtime server.
  - Depending on whether Excel or LibreOffice is installed, the information required for PDF creation was provided during the Runtime installation or in the "WinCC Unified Configuration" tool.

Procedure

1. Select the "Report jobs" tab in the "Reports" control.
2. Select "Add new" in the work area or click "Add new" in the toolbar.
3. In the detail area, enter a name for the report job.
4. Select a report template.
5. Configure the report name. See section Configuring report names (Page 7737).
   The configuration is applied to all reports generated by the report job.

6. Under "Targets", you determine how the reports are to be made available to users. Follow these steps:
   - Click "Add target".
     You see the targets configured in the tab "Job parameters > Targets".
   - Select a target.
   - Add the target by clicking "+".
     The target is added to the table to define the target formats.

   - Determine the formats in which the reports generated by the report job are provided for the target. In the table, activate the options of the desired formats for each target.

     Note

     Sending emails without a report

     If you deactivate both options for targets with "E-mail" target type, an email without attachment is sent after the report job has been executed.

     Note

     PDF as target type

     Generating PDFs with Excel is significantly slower than with LibreOffice. To generate large PDF reports, it is therefore recommended that you install LibreOffice.

     A PDF report created by LibreOffice can deviate in content or layout from a PDF report generated with Excel, for example, if the report template uses common Excel features that LibreOffice does not support, such as special fonts or chart types.

   - To remove a target from the report job, click the "Remove" button in the table.
7. Under "Trigger", select which event triggers the execution of the report job:
   - If the report job is only to be executed manually, select "Manual".
   - If the report job is to be executed automatically, select one of the other triggers configured under "Trigger".

     Note

     You can also execute the report job manually.

8. (Optional) Enter a comment for the report job.
9. Specify whether the automatic execution of the report job is active or paused. To do this, set the slider "Enabled" or "Disabled".

   Note

   You can still execute disabled report jobs manually.

Result

The report job is saved automatically.

When its trigger occurs, the report job is executed. A report is generated and made available as configured under "Targets".

Execution of report jobs (Page 7741)

Configure trigger (Page 7729)

Add target with target type "E-mail" (Page 7732)

Add a target with "File system" target type (Page 7733)

Tips on design and layout (Page 7717)

Managing report jobs

Requirement

- The "Reports" control is configured on a screen of the project.
- Report jobs have been configured in the control.

Procedure

1. Select the "Report jobs" tab in the "Reports" control.
2. To edit a report job, proceed as follows:
   - Select the report job in the work area.
   - In the detail area, edit the settings of the report job.
     You have the same options as when creating a report job.
3. To delete report jobs, proceed as follows:
   - In the work area, enable the options next to the report job.
   - Click "Delete" in the toolbar.

Configuring report names

Note

Make sure that the generated report name does not violate the policy of the operating system regarding the maximum length of file names.

Introduction

The default name of reports is `Report_{NNN}`.

To use different report names, enter one or more placeholders at the report job. The placeholders are combined to form the report name during execution of the report.

Placeholder types

Placeholders have one of the following types:

Placeholder type	Description	
Text	For user-defined fixed texts	
Counter	On automatic numbering	Dynamic placeholders The placeholders are broken down into values during execution of the report.
Date format	For outputting the generation time	
Tag	To output the process value of an online tag	

Unique report names

If the report name uses counter or date format placeholders, the report job generates unique report names.

Requirement

- The "Reports" control contains a screen of the runtime project that is running.

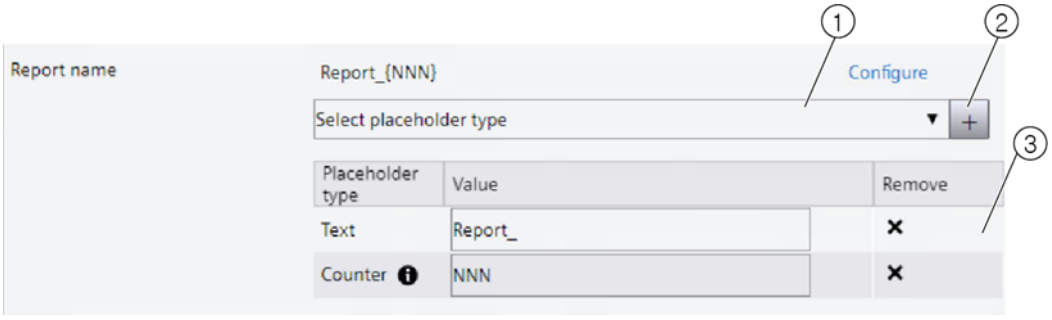
Procedure

You can enter the placeholders manually in the "Report name" field or you can have the software help you configure the report name.

To have the software help configure the report name, follow these steps:

1. Select the "Report jobs" tab in the "Reports" control.
2. Select a report job in the work area.
   You can see the settings for the report job in the detail area.

3. Next to "Report name", click "Configure".
   You see the following operator controls:



① List for selection of the placeholder type
② Button for adding a placeholder of the selected type
③ Table for configuring or removing the placeholder

Note

For the default report name, the "Report name" has the value `Report_{NNN}` and the table shows the placeholders "`Report_`" and "`NNN`".

To swap the order of placeholders or to add a placeholder in the center, delete the placeholders and then add them in the desired order.

4. Optional: To delete the default placeholders, click "x" in the placeholder table.
5. Select the desired type under "Select placeholder type".

Note

A report name can contain only one counter.

6. Click "+".
   An empty placeholder of the corresponding type is added at the end of the table.
7. Enter the placeholder under "Value" in the placeholder table.

Placeholder type	Description	Example
"Text"	Enter the text.	`Report_`
"Date format"	Enter a date placeholder.	A list of permitted placeholders and examples can be found in section Dynamic placeholder (Page 7746).
"Counter"	Enter a counter placeholder.	
"Tag"	Enter the full name of an online tag.	`RT1_Brewery::BatchNo`

Note

Enter the dynamic placeholders without any markup characters.

Alternatively, you can select an online tag via the user interface. Follow these steps:

– Click the "..." button on the tag placeholder.

– In the "Tag selection" dialog, click the "Search" button.
  You can see all the tags of the Runtime project that is running.

  Note

  Scrolling and filtering

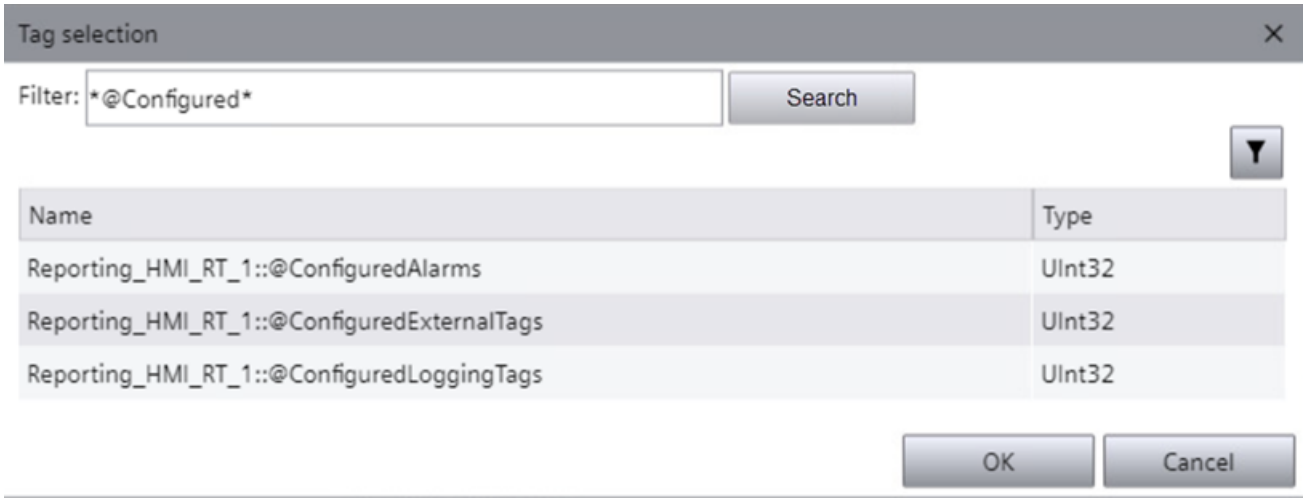
  Use the page navigation buttons to scroll forward or backward.

  To filter the displayed tags, enter a filter string in "Filter" and click "Search".

  You use the wildcard "*" to filter by partial strings.

  For example:
  - *T* returns all tags with a "T" in their name.
  - *T returns all tags that end in "T".
  - T* returns all tags that start with "T".

  When filtering for structures, the separators must be part of the filter string.



– Click the desired tag.

– Confirm with "OK".

In the "Report name" field, the placeholder you added is appended to the end of the report name.

Alternative procedure

To enter the placeholders manually, proceed as follows:

1. Select the "Report jobs" tab in the "Reports" control.
2. Select a report job in the work area.
   You can see the settings for the report job in the detail area.
3. Enter the desired combination of fixed texts and dynamic placeholders manually in the "Report name" field.
   Use markup characters for the dynamic placeholders. See section Dynamic placeholder (Page 7746).

Example:

"Report name" value	Generated report name
`Report_{yyyymmdd}_{HHMMss}_{@PC1_Brewery::BatchNo}`	`Report_20190101_170001_BatchNo_87002314`

Result

When generating a report, the dynamic placeholders are resolved and all placeholders are merged to form the report name.

If a process value contains a character that is not permitted in file names, it is replaced by an underscore.

If there is an error resolving the name, e.g. because the tag is not found in runtime, the tag placeholder in the name is replaced by `ERR`. The process is logged in the generation status of the report.

Execution of report jobs

Automatic and manual execution

Automatic execution

Report jobs that have a tag trigger, serial trigger or context trigger and are set to active on the "Report jobs" tab are automatically executed when their trigger occurs.

Manual execution

Report jobs with a trigger of the "Manual" type must always be executed manually.

In addition, you can at any time manually execute report jobs that have a tag trigger, serial trigger or context trigger.

System response to errors

- Error adding the report job to the queue
  The execution of the report job is discarded. A system alarm documents the error.
- Error executing the job
  In the "Reports" control, "Reports" tab, the status icon indicates the error. A click on the icon opens a detailed status message.
  A system alarm documents the error.

See also

Running a report job manually (Page 7742)

Configure trigger (Page 7729)

19.2.5.6 Running a report job manually

You can execute report jobs manually at any time, regardless of their trigger type. This also applies to report jobs that were disabled in the "Report Jobs" tab and whose automatic execution is therefore paused.

Requirement

Report jobs have been configured in the "Reports" control.

Procedure

1. Select the "Report jobs" tab in the "Reports" control.
2. In the work area, enable the option next to the report job that you want to execute manually.
3. Click "Execute" in the toolbar.

Result

The report is generated. You can download it in the "Reports" tab.

19.2.5.7 Downloading reports

You can download the reports stored by the report job in the file system to your device.

Depending on which file formats have been set in the report job, you can download the report as an XLSX file and as a PDF file.

Requirement

- Report jobs with the target type "File system" have been configured and executed in the "Reports" control.

Procedure

1. Select the "Reports" tab in the "Reports" control.
2. In the work area, select the option in the left column for each report that you want to download.
3. Enable the desired target formats in the "Files" column.

   Note

   Generation status

   You are only offered successfully generated formats.

   In the "Status" column you can check whether the generation for a format has failed. For a detailed status message click on the icon of a target format.

4. Click "Export" in the toolbar.

Result

The reports are downloaded into the download directory of the browser.

You can edit, distribute, or log the reports.

19.2.5.8 Exporting an offline configuration file

An offline configuration file is required to configure reporting templates in the Reporting Excel add-in without an online connection to the Runtime server.

Requirement

- The "Reports" control is placed on a screen of the project.
- The Runtime project has data that can serve as data source elements in the reporting template, such as alarms and logging tags.

Procedure

1. In the "Reports" control, click on the "Global settings > Configuration" tab.
2. Enter the name of the offline configuration file under "Offline-configuration".
3. Click "Export offline configuration".

Result

A JSON file with the data source elements of the Runtime project is created. The file is downloaded to the download folder or a user-defined directory according to the device settings.

You can select the configuration file in the Reporting Excel add-in as data source for an offline connection.

19.2.5.9 Transferring the control configuration

You have the option of reusing the settings in the "Reports" control, for example, on a device in another network. To do this, export the existing configuration on the one device from the control to a ZIP file. Then import the file into a "Reports" control on the other device.

Scope

The transfer covers the following data:

- Global settings, without passwords and certificates
- Job parameters, including the report templates available in the control
- Report jobs

Reports are not transferred.

Requirement

- The "Reports" control is placed on a screen in the project running in Runtime.
- Export: Settings have been made, e.g. contacts maintained, report templates imported, and report jobs created in the "Reports" control.
- Import: You have access to the ZIP file generated by the export on the device on which Runtime is installed.

Export configuration

1. In the "Reports" control, select the "Global settings > Configuration" tab.
2. Enter the name of the export file under "Export/import configuration > Export".
3. Click "Export configuration".

The configuration is exported to a ZIP file and downloaded to the default download directory of the device.

Import configuration

1. In the "Reports" control, select the "Global settings > Configuration" tab.
2. Click "Select import file" under "Export/import configuration".
3. Select the ZIP file in File Explorer and confirm your selection.
4. Runtime checks whether the control already contains configurations:
   - No: The configuration is imported.
   - Yes:
     Select "OK" to import the configuration. The existing configuration is overwritten.
     Select "Cancel" to cancel the import.

19.2.5.10 Configuring enable paging

To set how many entries the lists in the work area of the "Reports" control display per page, follow these steps:

1. In the "Reports" control, click on the "Global settings > Configuration" tab.
2. Under "List Settings", select the number of entries.

If a list has more entries, these are split over several pages. Use the buttons below the list to switch pages.

Note

The setting is lost through a screen change.

19.2.5.11 Inconsistencies and error diagnostics

Note

Inconsistent report jobs are not executed.

The templates available in the "Reports" control are not validated.

Display of inconsistencies and errors

Errors and inconsistencies are displayed as follows:

In the control	If job parameters are affected. Examples: • No template is set for a report job. • A tag that triggers a report job is deleted in the engineering system. The project is reloaded into the device.
In the "Error log" worksheet of the report	Errors or inconsistencies affecting the content of the report. Example: The report evaluates data from a tag that is no longer available in runtime.
As system alarm	For errors and inconsistencies that do not affect job parameters or the contents of the report. Example: The ExecuteReport system function transfers a report job that does not exist.

Job parameters

The following values lead to errors and inconsistencies:

Parameter	Invalid values	Default setting
"Name"	Zero, empty or already assigned name	"New report job"
"Template"	Zero, empty or "None". Name of a template that is not imported	"None"
"Target name"	Zero or empty	"NewReportJob[NN]"

19.2.5.12 Dynamic placeholder

Introduction

Dynamic placeholders are evaluated when the report job is executed and replaced with text in runtime.

The following job parameters can contain placeholders:

- Report name
- Targets with the target type "E-mail": Subject and text of the email

Dynamic placeholders for report names

Use dynamic placeholders for counters and/or dates to generate unique report names:

Counter placeholder	Description	Example		Area
		Configuration	Result	
{N}	Automatic numbering	Rep_{N}	Rep_1	0...9
{NN}		Rep_{NN}	Rep_01	00...99
{NNN}		Rep_{NNN}	Rep_001	000...999

Date placeholder	Description	Example		Area
		Configuration	Result	
{yy}	Current year	Rep_{yy}	Rep_18	Valid year with 2 digits
{yyyy}		Rep_{yyyy}	Rep_2018	Valid year with 4 digits
{m}	Current month	Rep_{m}	Rep_1	Valid month, no prefixed 0 for months in single-digit range
{mm}		Rep_{mm}	Rep_01	Valid month, prefixed 0 for months in single-digit range
{mmm}		Rep_{mm}	Rep_Jan	Month abbreviation with 3 characters
{mmmm}		Rep_{mmmm}	Rep_January	Month with full name

Date placeholder	Description	Example		Area
		Configuration	Result	
{d}	Current day of the month	Rep_{d}	Rep_1	Valid day, no prefixed 0 for days in single-digit range
{dd}		Rep_{dd}	Rep_01	Valid day, prefixed 0 for days in single-digit range
{ddd}		Rep_{ddd}	Rep_Mon	Day abbreviation with 3 characters
{dddd}		Rep_{dddd}	Rep_Monday	Day with full name
{h}	Current hour	Rep_{h}	Rep_1	Current hour (12-hour clock), no prefixed 0 for single-digit values
{hh}		Rep_{hh}	Rep_01	Current hour (12-hour clock), prefixed by 0 for single-digit values
{H}		Rep_{H}	Rep_13	Current hour (24-hour clock), no prefixed 0 for single-digit values
{HH}		Rep_{HH}	Rep_13	Current hour (24-hour clock), prefixed by 0 for single-digit values
{M}	Current minute	Rep_{M}	Rep_6	Valid minute, no prefixed 0 for single-digit values
{MM}		Rep_{MM}	Rep_06	Valid minute, prefixed by 0 for single-digit values
{s}	Current second	Rep_{s}	Rep_41	Valid second, no prefixed 0 for single-digit values
{ss}		Rep_{ss}	Rep_41	Valid second, prefixed by 0 for single-digit values

Use a dynamic placeholder for tags to integrate process values in the report name:

Tag placeholder	Description	Example		Area
		Configuration	Result	
{@<Full Tag name>}	Process value of an online tag	Rep_{@PC1_LineA::MyTag1}	Rep_On	Process value of the online tags If the value contains a character that is not permitted in file names, it is replaced by an underscore. If there is an error resolving the name, e.g. because the tag is not found in runtime, the tag placeholder in the name is replaced by `ERR`. The process is logged in the generation status of the report.

Examples:

Definition with placeholder	Generated report name
LineA_{yyyymmdd}_{HHMMss}	LineA_20190101_170001
LineA_{yymmmd}_{hhMMss}	LineA_19Jan1_050001
LineA_{NNN}	LineA_014
LineA_{yyyymmdd}_{HHMMss}_BatchNo_{@PC1_Brewery::BatchNo}	LineA_20190101_170001_BatchNo_87002314

Placeholder for email subject and email text

To integrate the report name into the subject line or the email text, use the following dynamic placeholder {ReportName}.

Markup

Use the following markup characters for dynamic placeholders:

- Placeholders for counter and date: `{ }`
- Placeholders for tags: `{@}`

Note

There is no markup in the placeholder table for defining the report name. See also section Configuring report names (Page 7737).

Runtime Openness 20

20.1 WinCC Unified Open Pipe

20.1.1 Introduction

Welcome to WinCC Unified Open Pipe

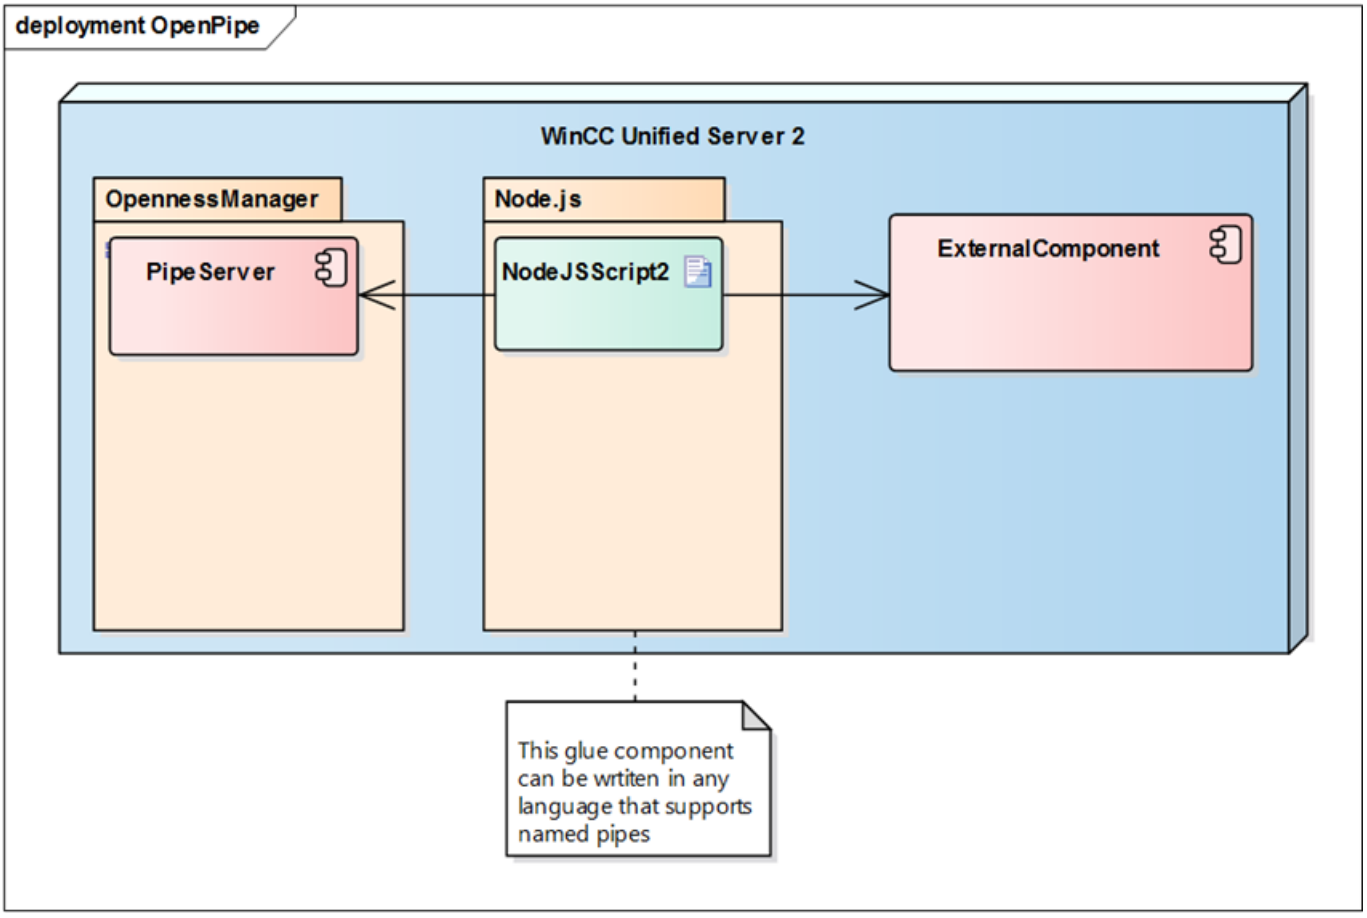
WinCC Unified Open Pipe is an Openness concept based on pipe technology to connect a customer application to WinCC Unified RT.

Compared to Openness RT (ODK), WinCC Unified Open Pipe offers a limited number of functions. However, the connection code can be written in any programming language that supports pipe technology. Even batch access to the pipe is possible.

The main aim of WinCC Unified Open Pipe is to make it possible for you to connect an existing application to WinCC Unified RT with little workload and independent of the programming language. The available commands let you communicate with WinCC Unified RT using tags and alarms.

Pipe technology

The pipe is a data stream with buffer between two processes that works according to the FIFO principle (First In First Out). One process is provided by WinCC Unified RT (OpennessManager). It creates the pipe and processes the requests of the customer application. The second process is the customer application. It connects to the pipe by using its name, sends requests and receives responses.



Name of the pipe:

- Under Windows: "\\.\pipe\HmiRuntime"
- Under Linux: "/tmp/HmiRuntime"

As soon as the pipe is open, single-line commands can be sent; they must end in a line break ("\n" or "\r\n"). Responses are returned using the same pipe instance.

Basic syntax and expert syntax

Two types of syntax are available for WinCC Unified Open Pipe:

- Basic syntax
  You use the basic syntax when you are working with basic batch files (e.g. in a CMD.exe or batch).
- Expert syntax
  You use the expert syntax when you are working with scripts or programming languages that have a JSON parser, e.g. Python, Node.js or Powershell.

Samples

You will find the following file on the installation medium:
"Support\Openness\Siemens.Unified.Openness_SDK_<version number>.zip"

Extract the file locally to any directory on your computer. You will then find examples of the use of WinCC Unified Open Pipe in the subfolder "OpenPipe\Samples".

20.1.2 Safety-related settings

Pipe access

- The use of Open Pipe is limited to local communication between the Open Pipe application and Runtime.
- To access the pipe, the user of the client script must belong to the following user group:
  - Under Windows: "SIMATIC HMI"
  - Under Linux: "industrial"

20.1.3 Behavior of the browse commands

Browse behavior

WinCC Unified Open Pipe provides several Browse commands in the simple syntax and in the expert syntax. The following behavior is common to all commands:

- Initial request
  In an initial request, you define the request using optional parameters.
- Page size
  To get the result faster, you can use a parameter to specify a page size in the initial request. If the result exceeds the specified page size, the response is distributed over several pages. Without this parameter the configured page size is used. You can read the configured page size via the commands "ReadConfig" and set it via "WriteConfig".

- Next request
  You get the next results page via the following requests. Next requests only have the parameter "Next".
- A Browse command is complete when a Next request returns an empty response.
- A Browse command that has not yet reached the last page of results is canceled in the following cases:
  - When the configured time limit for inactivity is exceeded.
    You can read the time limit via the commands ReadConfig and set it via WriteConfig.
  - When a new browse request is started.

Configurable settings

The following settings control the browse behavior:

Setting	Default value	Value range	Description
DefaultPageSize	1000	0 ... Uint32_Max	If a browse request was called without the PageSize parameter and the number of hits is greater than the value of DefaultPageSize, the response is distributed over several pages. Value 0: No pagination
BrowseTimeOut	300 s	0 ... Uint32_Max	For requests with pagination, defines after how many seconds without activity the request is canceled. After that a Next request returns an error. Value 0: No timeout

With the command "ReadConfig" you request the settings, with the command "WriteConfig" you set them. Changes apply to the current pipe session.

20.1.4 Using basic syntax

20.1.4.1 Basics of basic syntax

Characteristics

The basic syntax has the following characteristics:

- Simple text-based syntax without JSON parts.
- Only commands for individual objects, e.g. write access to a single tag.
- Object names may not include special characters or space characters.
- No cookies.

Structure of a request

`<Command> <Object> <Value>`

- `Command`: Command name, e.g. "WriteTagValue"
- `Object`: Name of the object for which the command is called, e.g. "Tag1"
- `Value`: Input value, e.g. "True"

Structure of a response

OnSuccess:

`Notify<Command> <Object> <Value1…ValueN>`

- `Command`: Command name, e.g. "ReadTagValue"
- `Object`: Name of the object for which the command was called, e.g. "Tag1"
- `Value1...ValueN`: For example, value and quality of the read tags

OnError:

`Error<Command> <Object> <Error text>`

- `Command`: Command name, e.g. "ReadTagValue"
- `Object`: Name of the object for which the command was called, e.g. "Tag1"
- `Error text`: Detailed error description

Overview of the commands of the simple syntax

Command	OnSuccess	OnError	Description
`SubscribeTagValue <Tag>`	`NotifySubscribeTagValue <Tag> <Quality> <Value>`	`ErrorSubscribeTagValue <Tag> <Error text>` `ErrorNotifyTagValue <Tag> <Error text>`	Subscribe tag for monitoring. `Quality`={good, bad, uncertain}
`UnsubscribeTagValue <Tag>`	`NotifyUnsubscribeTagValue <Tag>`	`ErrorUnsubscribeTagValue <Tag> <Error text>`	Unsubscribe tag from monitoring.
`ReadTagValue <Tag>`	`NotifyReadTagValue <Tag> <Quality> <Value>`	`ErrorReadTagValue <Tag> <Error text>`	Reads the value of the tags from the system.
`WriteTagValue <Tag> <Value>`	`NotifyWriteTagValue <Tag>`	`ErrorWriteTagValue <Tag> <Error text>`	Writes the value to the tag.
`SetCharSet <Value>`	`NotifySetCharSet <Value>`	`ErrorSetCharSet <Value> <Error text>`	Changes to a different character coding.
`ReadConfig <Parameter>`	`NotifyReadConfig <Parameter> <Value>`	`ErrorReadConfig <Error text>`	Reads a setting configured for the general browse behavior.
`WriteConfig <Parameter>`	`NotifyWriteConfig <Parameter> <Value>`	`ErrorWriteConfig <Error text>`	Sets a setting for the general browse behavior.

Command	OnSuccess	OnError	Description

`BrowseTags`:
• Initial request:
`BrowseTags <System> <Page size> --filter <Filter>`
• Next request:
`BrowseTags --next`
	`NotifyBrowseTags <System>::<Tag> ... <System>::<Tag>`	`ErrorBrowseTags <Error text>`	Returns the names of the tags of the local system or all systems communicating via runtime collaboration.

`BrowseConfiguredAlarms`:
• Initial request:
`BrowseConfiguredAlarms <System> <Page size> --filter <Filter>`
• Next request:
`BrowseConfiguredAlarms --next`
	`NotifyBrowseConfiguredAlarms <System>::<Alarm> ... <System>::<Alarm>`	`ErrorBrowseConfiguredAlarms <Error text>`	Returns the names of the configured alarms of the local system or all systems communicating via Runtime Collaboration.

`BrowseAlarmClasses <System>`	`NotifyBrowseAlarmClasses <System>::<Alarm class> ... <System>::<Alarm class>`	`ErrorBrowseConfiguredAlarms <Error text>`	Returns the alarm classes of the local system or all systems communicating via Runtime Collaboration.

Errors and error texts

This help only provides a selection of possible error messages. The error texts can also differ from the texts in your projects.

20.1.4.2 Commands

SubscribeTagValue

Description

The command "SubscribeTagValue" subscribes the specified tag for monitoring.

Error handling

- When the tag value contains a line break (\n), the value cannot be signaled. An error is signaled.
- When the same tag is subscribed a second time for monitoring, an error is signaled.

- A global monitoring error is signaled with "ErrorSubscribeTagValue". Because no monitoring was set up, there is no need to unsubscribe the tag from monitoring.
- An error relating to the tag value is signaled with "ErrorNotifyTagValue". Monitoring is set up in this case, but the tag value cannot be signaled for various reasons. Unsubscribe the tag from monitoring when it is no longer needed.

Request

```
SubscribeTagValue <Tag>
```

For example: `SubscribeTagValue Tag_1`

Response

OnSuccess (or partial success):

```
NotifySubscribeTagValue <Tag> <Quality> <Value>
```

For example:

- `NotifySubscribeTagValue Tag_1 Uncertain 0`
- `NotifySubscribeTagValue Tag_1 Good 10`
- `NotifySubscribeTagValue Tag_1 Bad 12`

OnError:

- Global error:
  `ErrorSubscribeTagValue <Tag> <Error text>`
  For example:
  - `ErrorSubscribeTagValue Tag_1 Tag does not exist`
  - `ErrorSubscribeTagValue Tag_1 Subscription already exists`
- Error for tag value:
  `ErrorNotifyTagValue <Tag> <Error text>`
  For example:
  - `ErrorNotifyTagValue Tag_1 Encoding error`
  - `ErrorNotifyTagValue Tag_1 Value contains newline`

UnsubscribeTagValue

Description

The "UnsubscribeTagValue" command unsubscribes a tag from monitoring.

Request

```
UnsubscribeTagValue <Tag>
```

For example: `UnsubscribeTagValue Tag_1`

Response

OnSuccess:

`NotifyUnsubscribeTagValue <Tag>`

For example:

- `NotifyUnsubscribeTagValue Tag_1`
- `NotifyUnsubscribeTagValue Tag_1`
- `NotifyUnsubscribeTagValue Tag_1`

OnError:

`ErrorUnsubscribeTagValue <Tag> <Error text>`

For example: `ErrorUnsubscribeTagValue Tag_1 Subscription does not exist`

ReadTagValue

Description

The "ReadTagValue" command reads the value of a tag from the system. Only the tag value and the quality are signaled.

When the tag value contains a line break (\n), the value cannot be signaled. An error is signaled.

Request

`ReadTagValue <Tag>`

For example: `ReadTagValue Tag_1`

Response

OnSuccess (or partial success):

`NotifyReadTagValue <Tag> <Quality> <Value>`

For example:

- `NotifyReadTagValue Tag_1 Uncertain 0`
- `NotifyReadTagValue Tag_1 Good 10`
- `NotifyReadTagValue Tag_1 Bad 12`

OnError:

`ErrorReadTagValue <Tag> <Error text>`

For example:

- `ErrorReadTagValue Tag_1 Tag does not exist`
- `ErrorReadTagValue Tag_1 Encoding error`
- `ErrorReadTagValue Tag_1 Value contains newline`

WriteTagValue

Description

The "WriteTagValue" command writes a value to a single tag.

When the transferred tag value contains a line break (\n), only the partial string in front of the line break is written to the tag.

Request

```
WriteTagValue <Tag> <Value>
```

For example: `WriteTagValue Motor.Label MC001`

Response

OnSuccess (or partial success):

```
NotifyWriteTagValue <Tag>
```

For example: `NotifyWriteTagValue Motor.Label`

OnError:

```
ErrorWriteTagValue <Tag> <Error text>
```

For example: `ErrorWriteTagValue Motor.Label Tag does not exist`

SetCharSet

Description

Sets the character encoding to one of the following specified values: {UTF-8, cp437, cp850}

The default character encoding is UTF-8.

The following character coding values must be supported as a minimum:

- UTF-8
- cp850
  In German Windows systems, this is the default for the SystemLocale.
- cp437
  In US Windows systems, this is the default for the SystemLocale.

Internally, strings are treated as Unicode strings (often as UTF-16 in a CFSTR). For external communication over the pipe, the Unicode characters must be converted into a byte representation.

When a character cannot be converted for a specific character coding (e.g. the Greek character "π" in the character coding cp437), an "encoding error" is triggered.

Request

```
SetCharSet <Value>
```

For example: `SetCharSet UTF-8`

Response

OnSuccess:

```
NotifySetCharSet <Value>
```

For example: `NotifySetCharSet UTF-8`

OnError:

```
ErrorSetCharSet <Value> <Error text>
```

For example: `ErrorSetCharSet UTF-9 unknown character set`

ReadConfig

Description

The "ReadConfig" command reads a setting configured for general browse behavior. To read multiple settings, call the command several times.

Request
`ReadConfig <Param>`

- `Param`:
  Value: The configuration parameters
  Possible parameters:
  - `DefaultPageSize`
    The page size used when a browse request is called without the "PageSize" parameter
  - `BrowseTimeOut`
    Number of seconds after which an inactive browse request is aborted.

For example:
`ReadConfig DefaultPageSize`

OnSuccess
`NotifyReadConfig <Parameter> <Value>`

For example:
```
NotifyReadConfig DefaultPageSize 1000
NotifyReadConfig BrowseTimeOut 300
```

OnError
`ErrorReadConfig <Error description>`

For example:
`ErrorReadConfig Invalid arguments passed to browsing function.`

WriteConfig

Description

The "WriteConfig" command sets a setting configured for general browse behavior. To set multiple settings, call the command several times

Request
`WriteConfig <Parameter> <Value>`

- `Parameter`:
  Value: The configuration parameters
  Possible parameters:
  - `DefaultPageSize`
    The page size used when a browse request is called without the "PageSize" parameter
    Preset value: 1000
  - `BrowseTimeOut`
    Number of seconds after which an inactive browse request is canceled.
    Preset value: 300 s

For example:
`WriteConfig DefaultPageSize 500`

Response

OnSuccess:
`NotifyWriteConfig <Parameter>`

For example:
`NotifyWriteConfig DefaultPageSize`

OnError:
`ErrorWriteConfig <Error description>`

For example:
`ErrorWriteConfig Invalid arguments passed to browsing function.`

BrowseTags

Description

The "BrowseTags" command returns the names of the tags of the local HMI system or all HMI systems communicating via runtime collaboration.

Information on the general browse behavior of the command can be found in section Behavior of the browse commands (Page 7751).

If the number of hits exceeds the page size of the response, the command consists of an initial request and 1 to N Next requests:

- You define the query in the initial request.
  It provides a response that delivers the first set of hits.
- You can call the remaining hits via Next requests.

Initial request

`BrowseTags <System> <Page size> --filter <Filter>`

- `System`: Optional
  Controls from which system the tags are read.
  - Value: "*"
    All systems that communicate with each other via runtime collaboration
  - Default value: The local system
- `Page size`: Optional
  Controls how many tags a response returns.
  Default value: The configured page size is used. See also section ReadConfig (Page 7758).
- `--filter <Filter>`: Optional
  Restricts the command to tags whose "Name" matches the filter.
  - `--filter`: Command line command
  - `<Filter>`: The filter string
    Permitted wildcards:

Wildcard	Description	Example
*	Replaces 0 to more characters	Filter string: "Motor*" Tags contained in the response: • "Motor" • "MotorOn" • "MotorOff"
?	Replaces 1 character	Filter string: "Motor_?" Tags contained in the response: • "Motor_1" • "Motor_2"

  - Default value: All tags of the system specified by `SystemNames` are queried.

For example:
```
BrowseTags * 100 --filter *Tag0* // browse for tags of all systems
with filter and paging
```

Next request

```
BrowseTags --next
```

Response

OnSuccess
```
NotifyBrowseTags <System>::<Tag name> ... <System>::<Tag name>
```

For example:
```
NotifyBrowseTags HMI_RT_1::InternalTag0 HMI_RT_2::InternalTag01
HMI_RT_2::InternalTag02
```

OnError
```
ErrorBrowseTags <Error description>
```

For example:
```
ErrorBrowseTags Invalid arguments passed to browsing function.
```

BrowseConfiguredAlarms

Description

The "BrowseConfiguredAlarms" command returns the names of the configured alarms of the local HMI system or all HMI systems communicating via Runtime Collaboration.

Information on the general browse behavior of the command can be found in section Behavior of the browse commands (Page 7751).

If the number of hits exceeds the page size of the response, the command consists of an initial request and 1 to N Next requests:

- You define the query in the initial request.
  It provides a response that delivers the first set of hits.
- You can call the remaining hits via Next requests.

Initial request

```
BrowseConfiguredAlarms <System> <Page size> --filter <Filter>
```

- `System`: Optional
  Controls from which system the alarms are read.
  - Value: "*"
    All systems that communicate with each other via runtime collaboration
  - Default value: The local system
- `Page size`: Optional
  Controls how many alarms a response returns.
  Default value: The configured page size is used. See also section ReadConfig (Page 7758).
- `--filter <Filter>`: Optional
  Restricts the command to alarms whose "Name" matches the filter.
  - `--filter`: Command line command
  - `<Filter>`: The filter string
    Permitted wildcards:

Wildcard	Description	Example
*	Replaces 0 to more characters	Filter string: "Motor*:Analog_Alarm" Alarms contained in the response: • "MotorOn:AnalogAlarm" • "MotorOff:AnalogAlarm"
?	Replaces 1 character	Filter string: "Motor_?:Analog_alarm" Alarms contained in the response: • "Motor_1:Analog_alarm" • "Motor_2:Analog_alarm"

  - Default value: All tags of the system specified by `SystemNames` are queried.

For example:
```
BrowseConfiguredAlarms * 100 --filter *Analog* // browse for alarms
of all systems with filter and paging
```

Next request

```
BrowseConfiguredAlarms --next
```

Response

OnSuccess
```
NotifyBBrowseConfiguredAlarms <System>::<Alarm name> ...
<System>::<Alarm name>
```

For example:
```
NotifyBrowseConfiguredAlarms HMI_RT_1::Motor_1:AnalogAlarm_1
HMI_RT_2::Motor_1:AnalogAlarm_1 HMI_RT_2::Motor_2:AnalogAlarm_1
```

OnError
`ErrorBrowseConfiguredAlarms <Error description>`

For example:
```
ErrorBrowseConfiguredAlarms A parameter is not valid or out of
range.
```

BrowseAlarmClasses

Description

The command "`BrowseAlarmClasses`" returns the alarm classes of the local HMI system or all HMI systems communicating via Runtime Collaboration.

Information on the general browse behavior of the command can be found in section Behavior of the browse commands (Page 7751).

Note

Paging is not available for "BrowseAlarmClasses".

Request

`BrowseAlarmClasses <System>`

- `System`: Optional
  Controls from which system the tags are read.
  - Value: "*"
    All systems that communicate with each other via runtime collaboration
  - Default value: The local system

For example:

```
BrowseAlarmClasses  //Browse for alarm classes in local system
```

Response

OnSuccess
`NotifyBrowseAlarmClasses <System>::<Alarm class> ... <System>::<Alarm class>`

For example:
```
NotifyBrowseAlarmClasses HMI_RT_1::Alarm
HMI_RT_1::SystemNotification HMI_RT_1::SystemInformation
HMI_RT_1::SystemAlarm HMI_RT_1::Notification
HMI_RT_1::OperatorInputInformation
```

OnError
`ErrorBrowseAlarmClasses <Error description>`

For example:
```
ErrorBrowseAlarmClasses Invalid arguments passed to browsing
function.
```

ReadConfig (Page 7758)

20.1.4.3 Reference

The following section contains a reference of the properties of tags that you get with the command ReadTagValue.

The commands transfer the property values as string.

Tag properties

"Name" property

Name of the tag

"Value" property

Value of the tag at the moment of the read operation.

"Quality" property

Quality of the read operation of the tag

Possible values:

- "Good"
- "Bad"
- "Uncertain"

"ErrorDescription" property

Description of the error code of the last read or write operation of the tag

20.1.5 Using expert syntax

20.1.5.1 Basics of expert syntax

Characteristics

The expert syntax has the following characteristics:

- Complete JSON commands and replies.
- Commands for individual objects and multiple objects, for example, to write multiple tags in one call.
- Character coding is always UTF-8.
- Cookies are available and mandatory.

Structure of a request

```
{
  "Message": "<Command>",
  "Params":
  {
      "<Object name>":
      [
        "<Param1>",
        "<Param2>"
      ]
  },
  "ClientCookie": "<Cookie name>"
}
```

Structure of a response

OnSuccess

```
{
  "Message": "Notify<Command>",
  "Params":
  {
      "<Object name>":
    [
      {
        "<Value1>"
      },
      {
        "<Value2>"
      }
    ]
  },
  "ClientCookie": "<Cookie name>"
}
```

OnError

```
{
 "Message": "Error<Command>",
```

```
 "ErrorCode": "<Error code>",
 "ErrorDescription": "<Error description>",
 "ClientCookie": "<Cookie name>"
}
```

Overview of the commands of the expert syntax

Command	OnSuccess	OnError	Description
`SubscribeTag <Tag> <ClientCookie>`	`NotifySubscribeTag <Tag name> <Value> <TimeStamp> <Quality> <QualityCode> <hasChanged> <Error code> <Error text> <ClientCookie>`	`ErrorSubscribeTag <Error code> <Error text> <ClientCookie>`	Subscribes one or more tags for monitoring.
`UnsubscribeTag <ClientCookie>`	`NotifyUnsubscribeTag <ClientCookie>`	`ErrorUnsubscribeTag <Error code> <Error text> <ClientCookie>`	Unsubscribes the tag or tags from the cookie from monitoring.
`ReadTag <Tags> <ClientCookie>`	`NotifyReadTag <Tag name> <Value> <TimeStamp> <Quality> <QualityCode> <Errorcode> <Error text> <ClientCookie>`	`ErrorReadTag <Error code> <Error text> <ClientCookie>`	Reads the value of one or more tags of the system.
`WriteTag <Tags, Values> <ClientCookie>`	`NotifyWriteTag <Tag name> <Error code> <Error text> <ClientCookie>`	`ErrorWriteTag <Error code> <Error text> <ClientCookie>`	Writes the specified values to the specified tags.
`SubscribeAlarm <Filter> <Systems> <Language> <ClientCookie>`	`NotifySubscribeAlarm <ClientCookie> <Alarms>`	`ErrorSubscribeAlarm <Error code> <Error text> <ClientCookie>`	Subscribes the alarms defined over the filter, the system and the language ID for monitoring.
`UnsubscribeAlarm <ClientCookie>`	`NotifyUnsubscribeAlarm <ClientCookie>`	`Error UnsubscribeAlarm <Error code> <Error text> <ClientCookie>`	Unsubscribes the alarms from the cookie from monitoring.
`ReadAlarm <Filter> <Systems> <Language> <ClientCookie>`	`NotifyReadAlarm <ClientCookie> <Alarms>`	`ErrorReadAlarm <Error code> <Error text> <ClientCookie>`	Reads the alarms defined by the filter, the system and the LanguageID.

Command	OnSuccess	OnError	Description
`ReadConfig <Parameter> <ClientCookie>`	`NotifyReadConfig <Parameter> <Value> <ClientCookie>`	`ErrorReadConfig <Error code> <Error text> <ClientCookie>`	Reads the settings configured for the general browse behavior.
`WriteConfig <Parameter> <ClientCookie>`	`NotifyWriteConfig <Parameter> <Value> <ClientCookie>`	`ErrorWriteConfig <Error code> <Error text><ClientCookie>`	Sets the settings for the general browse behavior.
`BrowseTags` • Initial request: `BrowseTags <LanguageId> <Filter> <Attribute> <PageSize> <Systems> <ClientCookie>` • Next request: `BrowseTags <Next> <ClientCookie>`	`NotifyBrowseTags <Attribute> <Value> ... <Attribute> <Value> <ClientCookie>`	`ErrorBrowseTags <Error code> <Error text> <ClientCookie>`	Returns "Name", "DisplayName" and "DataType" as well as optional additional attribute values of the tags of the local system or several HMI systems communicating via runtime collaboration.
`BrowseConfiguredAlarms:` • Initial request: `BrowseConfiguredAlarms <LanguageId> <Filter> <Attributes> <PageSize> <SystemNames> <ClientCookie>` • Next request: `BrowseConfiguredAlarms <Next> <ClientCookie>`	`NotifyBrowseConfiguredAlarms <Alarm class> <Alarms> ... <Alarm class> <Alarms> <ClientCookie>`	`ErrorBrowseConfiguredAlarms <Error code> <Error text> <ClientCookie>`	Returns "AlarmClass", "Name" and "Area" as well as optional further attribute values of the configured alarms of an HMI system or several systems communicating via Runtime Collaboration.
`BrowseAlarmClasses <Filter> <Attributes> <Systems>`	`NotifyBrowseAlarmClasses <Alarm class> ... <Alarm class> <ClientCookie>`	`ErrorBrowseAlarmClasses <Error code> <Error text> <ClientCookie>`	Returns the alarm classes of the local system or all systems communicating via Runtime Collaboration.

Errors and error texts

This help only provides a selection of possible error messages. The error texts can also differ from the texts in your projects.

Attributes of the tags and alarms

You can find a description of the attributes of the tags and alarms in the help document Runtime - Open Development Kit (ODK) (Page 7822).

20.1.5.2 Commands

SubscribeTag

Description

The "SubscribeTag" command subscribes one or more tags for monitoring. The following properties are monitored:

- Tag value
- Quality
- Quality code
- Time stamp

"NotifiySubscribeTag" always returns all monitored tags, even if only the value of one monitored tag changes. The change can be a change to the quality code, time stamp or tag value. The order of tags in the response corresponds to the order in the "SubscribeTag" request.

It is permitted to have the same tag monitored by multiple "SubscribeTag" calls.

Request

```
{"Message":"SubscribeTag","Params":{"Tags":
["<Tag>","<Tag>"]},"ClientCookie":"<Cookie>"}
```

- `Tags`: List of the tags to be monitored
- `ClientCookie`: Is used for "UnsubscribeTag" and to assign the notification to its monitoring.

For example:

```
{"Message":"SubscribeTag","Params":{"Tags":
["Tag_0","Tag_1"]},"ClientCookie":"mySubscription1"}
```

Response

OnSuccess

```
{"Message":"NotifySubscribeTag", "Params":{"Tags":[{"Name":"<Tag>",
"Quality":"<Value>", "QualityCode":"<Value>",
"TimeStamp":"<Value>", "Value":"<Tag value>",
"ErrorCode":<Value>, "ErrorDescription":"<Error text>"},
{"Name":"<Tag>", "Quality":"<Value>", "QualityCode":"<Value>",
"TimeStamp":"<Value>", "Value":"<Tag value>", "ErrorCode":<Value>,
"ErrorDescription":"<Error text>"}]}, "ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"NotifySubscribeTag", "Params":{"Tags":[{"Name":"Tag_0",
"Quality":"Good", "QualityCode":"192",
"TimeStamp":"2019-01-30T11:25:35Z", "Value":"16", "ErrorCode":0,
"ErrorDescription":""}, {"Name":"Tag_1", "Quality":"Uncertain",
"QualityCode":"76", "TimeStamp":"2019-01-30T11:25:35Z",
```

```
"Value":"1", "ErrorCode":-2147483620, "ErrorDescription":"Tag does
not exist"}]}, "ClientCookie":"mySubscription1"}
```

OnError

```
{"Message":"ErrorSubscribeTag", "ErrorCode":<Value>,
"ErrorDescription":"<Error text>", "ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"ErrorSubscribeTag", "ErrorCode":-2147483621,
"ErrorDescription":"Subscription could not be created",
"ClientCookie":"mySubscription1"}
```

UnsubscribeTag

Description

The "UnsubscribeTag" command unsubscribes a tag from monitoring that was started with the cookie transferred in the call of "SubscribeTag".

Request

```
{"Message":"UnsubscribeTag","ClientCookie":"<Cookie>"}
```

For example:
```
{"Message":"UnsubscribeTag","ClientCookie":"mySubscription1"}
```

Response

OnSuccess

```
{"Message":"NotifyUnsubscribeTag","ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"NotifyUnsubscribeTag","ClientCookie":"mySubscription1"}
```

OnError

```
{"Message":"ErrorUnsubscribeTag", "ErrorCode":<Value>,
"ErrorDescription":"<Error text>", "ClientCookie":"Cookie"}
```

For example:

```
{"Message":"ErrorUnsubscribeTag", "ErrorCode":-2147483621,
"ErrorDescription":"Subscription could not be closed",
"ClientCookie":"mySubscription1"}
```

ReadTag

Description

The "ReadTag" command reads multiple tags. The tag value, the quality, the quality code and the time stamp are signaled.

The order of tags in the response corresponds to the order in the "ReadTag" request.

Request

```
{"Message":"ReadTag","Params":{"Tags":
["<Tag>","<Tag>"]},"ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"ReadTag","Params":{"Tags":
["Tag_0","Tag_1"]},"ClientCookie":"myRequest1"}
```

Response

OnSuccess

```
{"Message":"NotifyReadTag","Params":{"Tags":
[{"Name":"<Tag>","Quality":"<Value>","QualityCode":"<Value>","TimeSt
amp":"<Value>","Value":"<TagValue>","ErrorCode":<Value>,"ErrorDescri
ption":"<ErrorText>"},
{"Name":"<Tag>","Quality":"<Value>","QualityCode":"<Value>","TimeSta
mp":"<Value>","Value":"<TagValue>","ErrorCode":<Value>,"ErrorDescrip
tion":"<ErrorText>"}]},"ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"NotifyReadTag","Params":{"Tags":
[{"Name":"Tag_0","Quality":"Good","QualityCode":"192","TimeStamp":"2
019-01-30T11:25:35Z","Value":"16","ErrorCode":0,"ErrorDescription":"
"},
{"Name":"Tag_1","Quality":"Uncertain","QualityCode":"76","TimeStamp"
:"2019-01-30T11:25:35Z","Value":"1","ErrorCode":-2147483620,"ErrorDe
scription":"Tag does not exist"}]},"ClientCookie":"myRequest1"}
```

OnError

```
{"Message":"ErrorReadTag","ErrorCode":<Value>,"ErrorDescription":"<E
rror text>", "ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"ErrorReadTag","ErrorCode":-2147483621,"ErrorDescription"
:"Failed to Read", "ClientCookie":"myRequest1"}
```

WriteTag

Description

The "WriteTag" command writes the values of multiple tags.

Request

```
{"Message":"WriteTag","Params":{"Tags":
[{"Name":"<Tag>","Value":"<Tag value>"},
{"Name":"<Tag>","Value":"<Tag value>"}]},"ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"WriteTag","Params":
{"Tags":[{"Name":"Tag_0","Value":"50"},
{"Name":"Tag_1","Value":"40"}]},"ClientCookie":"myRequest2"}
```

Response

OnSuccess

```
{"Message":"NotifyWriteTag","Params":{"Tags":
[{"Name":"<Tag>","ErrorCode":<Value>,"ErrorDescription":"<ErrorText>
"},
{"Name":"<Tag>","ErrorCode":<Value>,"ErrorDescription":"<ErrorText>"
}]},"ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"NotifyWriteTag","Params":{"Tags":
[{"Name":"Tag_0","ErrorCode":0,"ErrorDescription":""},
{"Name":"Tag_1","ErrorCode":-2147483620,"ErrorDescription":"Tag
does not exist"}]},"ClientCookie":"myRequest2"}
```

OnError

```
{"Message":"ErrorWriteTag","ErrorCode":<Value>,"ErrorDescription":"<
Error text>", "ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"ErrorWriteTag","ErrorCode":-2147483621,"ErrorDescription
":"Failed to Write", "ClientCookie":"myRequest2"}
```

SubscribeAlarm

Description

The "SubscribeAlarm" command subscribes systems for monitoring of changes of active alarms.

The first time "NotifySubscribeAlarm" is called, all active alarms are queried. Afterwards "NotifySubscribeAlarm" is only called if the status of an alarm changes.

Request

```
{"Message":"SubscribeAlarm","Params":{"SystemNames":
["<System>","<System>"],"Filter":"<Filter>","LanguageId":<ID>},"Clie
ntCookie":"<Cookie>"}
```

- `SystemNames`: Optional
  When the list is empty or missing, all known systems are subscribed for monitoring.
- `Filter`: Optional
- `LanguageID`: Optional
- `ClientCookie`:
  Is used for "UnsubscribeAlarm" and to assign the notification to its monitoring.

For example:

```
{"Message":"SubscribeAlarm","Params":{"SystemNames":
["System0","System1"],"Filter":"AlarmClassName !=
'Warning'","LanguageId":1033},"ClientCookie":"CookieForSubscribeAlar
ms123"}
```

Response

OnSuccess

```
{"Message":"NotifySubscribeAlarm","ClientCookie":"<Cookie>","params"
:{"Alarms":[{<Key value pairs for the properties of the first
alarm>},{<Key value pairs for the properties of the second alarm>},
{<...>}]}}
```

For example:

```
{"Message":"NotifySubscribeAlarm","ClientCookie":"CookieForSubscribe
Alarms123","params":{"Alarms":[{"AcknowledgmentTime":"1970-01-01
00:00:00.0000000","AlarmClassName":"Alarm","AlarmClassSymbol":"Alarm

```

OnError

```
{"Message":"ErrorSubscribeTag", "ErrorCode":<Value>,
"ErrorDescription":"<Error text>", "ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"ErrorSubscribeAlarm","ErrorCode":"-2147483621","ErrorDes
cription":"Alarm Subscription failed because of invalid
filter","ClientCookie":"CookieForSubscribeAlarms123"}
```

UnsubscribeAlarm

Description

The "UnsubscribeAlarm" command unsubscribes the alarms from monitoring that was started with the cookie transferred in the call of "SubscribeAlarm".

Request

```
{"Message":"UnsubscribeAlarm","ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"UnsubscribeAlarm","ClientCookie":"CookieForSubscribeAlar
ms123"}
```

Response

OnSuccess

```
{"Message":"NotifyUnsubscribeAlarm","ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"NotifyUnsubscribeAlarm","ClientCookie":"CookieForSubscri
beAlarms123"}
```

OnError

```
{"Message":”ErrorUnsubscribeAlarm","ErrorCode":<Value>,"ErrorDescrip
tion":"<Error text>", "ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"ErrorUnsubscribeAlarm","ErrorCode":-2147483621,"ErrorDes
cription":"Subscription could not be closed",
"ClientCookie":"CookieForSubscribeAlarms123"}
```

ReadAlarm

Description

The "ReadAlarm" command reads all active alarms.

Request

```
{"Message":"ReadAlarm","Params":{"SystemNames":
["<System>","<System>"],"Filter":"<Value>","LanguageId":<Value>},"Cl
ientCookie":"<Cookie>"}
```

- `SystemNames`: Optional
  When the list is empty or missing, all known systems are subscribed for monitoring.
- `Filter`: Optional
- `LanguageID`: Optional
- `ClientCookie`:
  Is used for "UnsubscribeAlarm" and to assign the notification to its monitoring.

For example:

```
{"Message":"ReadAlarm","Params":{"SystemNames":
["System0","System1"],"Filter":"","LanguageId":1033},"ClientCookie":
"CookieForReadAlarmRequest456"}
```

Response

```
{"Message":"NotifyReadAlarm", "ClientCookie":"<Cookie>","params":
{"Alarms":[{<Key value pairs for properties of the first alarm>},
{<Key value pairs for the properties of the second alarm>},
{<...>}]}}
```

OnSuccess

For example:

```
{"Message":"NotifyReadAlarm",
"ClientCookie":"CookieForReadAlarmRequest456", "params":{"Alarms":
[{"AcknowledgmentTime":"1970-01-01 00:00:00.0000000",

configured.","ValueQuality":"192"", "AlarmGroupID": "1"}]}
```

OnError

```
{"Message":"ErrorReadAlarm","ErrorCode":<Value>,
"ErrorDescription":"<Error text>", "ClientCookie":"<Cookie>"}
```

For example:

```
{"Message":"ErrorReadAlarm","ErrorCode":-2147483621,
"ErrorDescription":"Alarm Subscription failed because of invalid
filter", "ClientCookie":"CookieForReadAlarmRequest456"}
```

ReadConfig

Description

The "ReadConfig" command reads the settings configured for the general browse behavior.

Request

```
{"Message": "ReadConfig",  "Params": ['<Parameter>',
'<Parameter>'],  "ClientCookie": '<Cookie>'}
```

- `Params`:
  Value: Comma-separated list of configuration parameters
  Possible parameters:
  - `DefaultPageSize`
    The page size used when a browse request is called without the "PageSize" parameter
  - `BrowseTimeOut`
    Number of seconds after which an inactive browse request is canceled.
- `Cookie`:
  Name of the response cookie

For example:

```
{"Message": "ReadConfig", "Params": ['DefaultPageSize',
'BrowseTimout'], "ClientCookie": "myBrowseAlarmsRequest1"}
```

OnSuccess

```
{"Message":"NotifyReadConfig", "Params": {"<Parameter>":<Value>,
"<Parameter>":<Value>}, "ClientCookie": '<Cookie>'}
```

For example:
```
{"Message":"NotifyReadConfig", "Params": {"DefaultPageSize":500,
"BrowseTimeOut":60}, "ClientCookie": "myBrowseAlarmsRequest1"}
```

OnError
```
{"Message": "ErrorReadConfig",  "ErrorCode": "<Code>",
"ErrorDescription": "<Description>", "ClientCookie": "<Cookie>"}
```

For example:
```
{"Message": "ErrorReadConfig",  "ErrorCode": "-2165322729",
"ErrorDescription": "Invalid arguments passed to browsing
function.", "ClientCookie": "myBrowseAlarmsRequest1"}
```

WriteConfig

Description

The "WriteConfig" command sets configurable settings for the general browse behavior.

Request
```
{"Message": "WriteConfig",  "Params": ["<Parameter>":<Value>,
"<Parameter>":<Value>],  "ClientCookie": '<Cookie>'}
```

- `Params`:
  Value: Comma-separated list of configuration parameters and their values
  Possible parameters:
  - `DefaultPageSize`
    The page size used when a browse request is called without the "PageSize" parameter
    Preset value: 1000
  - `BrowseTimeOut`
    Number of seconds after which an inactive browse request is canceled.
    Preset value: 300 s
- `Cookie`:
  Name of the response cookie

For example:
```
{"Message": "WriteConfig", "Params": ["DefaultPageSize":500,
"BrowseTimout":60], "ClientCookie": "myBrowseAlarmsRequest1"}
```

OnSuccess
```
{"Message":"NotifyWriteConfig", "Params": {"<Parameter>":<Value>,
"<Parameter>":<Value>}, "ClientCookie": '<Cookie>'}
```

For example:
```
{"Message":"NotifyWriteConfig", "Params": {"DefaultPageSize":500,
"BrowseTimeOut":60}, "ClientCookie": "myBrowseAlarmsRequest1"}
```

OnError
```
{"Message": "ErrorWriteConfig",  "ErrorCode": "<Code>",
"ErrorDescription": "<Description>" "ClientCookie": "<Cookie>"}
```

For example:

```
{"Message": "ErrorWriteConfig",  "ErrorCode": "-2165322733",
"ErrorDescription": "A parameter is not valid or out of range.",
"ClientCookie": "myBrowseAlarmsRequest1"}
```

BrowseTags

Description

The "BrowseTags" command returns "Name", "DisplayName" and "DataType" as well as optional further attribute values of the tags of an HMI system or several HMI systems communicating via runtime collaboration.

Information on the general browse behavior of the command can be found in section Behavior of the browse commands (Page 7751).

If the number of hits exceeds the page size of the response, the command consists of an initial request and 1 to N Next requests:

- You define the query in the initial request.
  It provides a response that delivers the first set of hits.
- You can call the remaining hits via Next requests.

Initial request

```
{"Message": "BrowseTags",  "Params": {"LanguageId": <Value>,
"Filter": "<String>", "Attributes": ["<Attribute name>", ...,
"<Attribute name>"], "PageSize": <Value>, "SystemNames":
["<Name>",  ..., "<Name>"]}, "ClientCookie": "<Cookie>"}
```

- `LanguageId`: Optional
  Controls in which language the "DisplayName" of the tags is returned.
  - Value: The language ID
  - Default value: The default language of the system from which the tag originates
- `Filter`: Optional
  Restricts the command to tags whose "Name" matches the filter.
  - Value: Filter string
    Permitted wildcards:

Wildcard	Description	Example
*	Replaces 0 to more characters	Filter string: "Motor*" Tags contained in the response: • "Motor" • "MotorOn" • "MotorOff"
?	Replaces 1 character	Filter string: "Motor_?" Tags contained in the response: • "Motor_1" • "Motor_2"

  - Default value: All tags of the system specified by `SystemNames` are queried.
- `Attributes`: Optional
  Controls which tag attributes returns the response:
  - Value: Comma-separated enumeration of the attribute names
    The response returns "Name", "DisplayName" and "DataType" as well as the specified attributes.
  - Value: "*"
    The response provides all attributes supported by the TIA Portal for tags: Name, DisplayName, AcquisitionMode, Persistent, DataType, Connection, AcquisitionCycle, MaxLength, SubstituteValueUsage, InitialValue, SubstituteValue, InitialMaxValue, InitialMinValue, Address
  - Default value: The response returns "Name", "DisplayName" and "DataType".
- `PageSize`: Optional
  Controls how many tags a response returns.
  Default value: The configured page size is used. See also section ReadConfig (Page 7775).

- `SystemNames`: Optional
  Controls from which system the tags are read.
  - Value: "*"
    All systems that communicate with each other via runtime collaboration
  - Value: Comma-separated list of systems that communicate with each other via runtime collaboration
    FOR EXAMPLE: "HMI_RT_1", "HMI_RT_2"
  - Default value: The local system
- `ClientCookie`:
  Value: Name of the response cookie

For example:
```
{"Message": "BrowseTags",  "Params": {"LanguageId": 1033,
"Filter": "*InternalTag_Bool_1*", "Attributes": ["AcquisitionMode",
"MaxValue"], "PageSize": 50, "SystemNames": ["HMI_RT_1",
"HMI_RT_2"]}, "ClientCookie": "myBrowseTagRequest1"}
```

Next request

```
{"Message": "BrowseTags", "Params": "Next", "ClientCookie":
"<Cookie>"}
```

For example:
```
{"Message": "BrowseTags", "Params": "Next", "ClientCookie":
"myBrowseTagRequest1"}
```

Response

OnSuccess
```
{"ClientCookie": "<Cookie>", "Message": "NotifyBrowseTags",
"Params": {"Tags": [{"<Attribute name":<Value>, "<Attribute
name>":<Value>, "DataType":<Value>, "DisplayName": "<Value>",
"Name":"<Value>"}],}}
```

For example:
```
{"ClientCookie": "<myBrowseTagRequest1>", "Message":
"NotifyBrowseTags", "Params": {"Tags":
[{"AcquisitionMode":0, "MaxValue":1000, "DataType":1,
"DisplayName": "HMI_RT_1::InternalTag_Bool_1",
"Name":"HMI_RT_1::InternalTag_Bool_1"}],}}
```

OnError
```
{"Message": "ErrorBrowseTags", "ErrorCode": "<Code>",
"ErrorDescription": "<Description>", "ClientCookie": "Cookie>"}
```

For example:
```
{"Message": "ErrorBrowseTags", "ErrorCode": "-2165323798",
"ErrorDescription": "Invalid system name.", "ClientCookie":
myBrowseTagRequest1"}
```

BrowseConfiguredAlarms

Description

The "BrowseConfiguredAlarms" command returns "AlarmClass", "Name" and "Area" as well as optional further attribute values of the configured alarms of an HMI system or several systems communicating via Runtime Collaboration.

Information on the general browse behavior of the command can be found in section Behavior of the browse commands (Page 7751).

If the number of hits exceeds the page size of the response, the command consists of an initial request and 1 to N Next requests:

- You define the query in the initial request.
  It provides a response that delivers the first set of hits.
- You can call the remaining hits via Next requests.

Initial request

```
{"Message": "BrowseConfiguredAlarms",  "Params": {"LanguageId":
<Value>, "Filter": "<String>", "Attributes": ["<Attribute
name>", ..., "<Attribute name>"], "PageSize": <Value>,
"SystemNames": ["<Name>", ..., "<Name>"]}, "ClientCookie":
"<Cookie>"}
```

- `LanguageId`: Optional
  Controls in which language the alarm texts are returned.
  - Value: The language ID
  - Default value: The default language of the system from which the alarm originates
- `Filter`: Optional
  Restricts the command to alarms whose "Name" matches the filter.
  - Value: Filter string
    Permitted wildcards:

Wildcard	Description	Example
*	Replaces 0 to more characters	Filter string: "Motor*:Analog_Alarm" Alarms contained in the response: • "MotorOn:AnalogAlarm" • "MotorOff:AnalogAlarm"
?	Replaces 1 character	Filter string: "Motor_?:Analog_alarm" Alarms contained in the response: • "Motor_1:Analog_alarm" • "Motor_2:Analog_alarm"

  - Default value: All alarms of the system specified by `SystemNames` are queried.

- `Attributes`: Optional
  Controls which alarm attributes the response returns:
  - Value: Comma-separated enumeration of the attribute names
    The response returns "AlarmClass", "Name" and "Area" as well as the specified attributes.
  - Value: "*"
    The response returns the following attributes: Name, ID, SourceType, AlarmClassName, Priority, EventText, AlarmText1, AlarmText2, AlarmText3, AlarmText4, AlarmText5, AlarmText6, AlarmText7, AlarmText8, AlarmText9, InfoText, Group, Origin, Area
  - Default: The response returns "AlarmClass", "Name" and "Area".
- `PageSize`: Optional
  Controls how many alarms a response returns.
  Default value: The configured page size is used. See also section ReadConfig (Page 7775).
- `SystemNames`: Optional
  Controls from which system the alarms are read.
  - Value: "*"
    All systems that communicate with each other via runtime collaboration
  - Value: Comma-separated list of systems that communicate with each other via runtime collaboration
    FOR EXAMPLE: "HMI_RT_1", "HMI_RT_2"
  - Default value: The local system
- `ClientCookie`:
  Value: Name of the response cookie

For example:
```
{"Message": "BrowseConfiguredAlarms", "Params": {"LanguageId":
1033, "Filter": "*alarm_*", "Attributes": ["Priority"],
"PageSize": 50, "SystemNames": ["HMI_RT_1"], }, "ClientCookie":
"myBrowseAlarmsRequest1"}
```

Next request

```
{"Message": "BrowseConfiguredAlarms", "Params": "Next",
"ClientCookie": "<Cookie>"}
```

For example:
```
{"Message": "BrowseConfiguredAlarms", "Params": "Next",
"ClientCookie": "myBrowseAlarmsRequest1"}
```

Response

OnSuccess
```
{"ClientCookie": "<Cookie>", "Message":
"NotifyBrowseConfiguredAlarms", "Params":
{"AlarmClasses":[{"AlarmClassName":"<Value>", "Alarms":
[{"AlarmClassName":"<Value>", "Area":<Value>, "Name":<Value>,
"Name":<Value>, "Priority":<Value>}, {"AlarmClassName":"<Value>",
"Area":<Value>, ...}], {"AlarmClassName":"<Value>", "Alarms":
[{"AlarmClassName": "<Value>, ...}]}
```

For example:
```
{"ClientCookie":"myBrowseAlarmsRequest1",
"Message":"NotifyBrowseConfiguredAlarms", "Params":{"AlarmClasses":
[{"Name":"HMI_RT_1::Warning",
"Alarms":[{"AlarmClassName":"HMI_RT_1::Warning",
"Area":"HMI_RT_1::Alarming",
"Name":"HMI_RT_1::Tag6:Analog_alarm_2", "Priority":12},
{"AlarmClassName":"HMI_RT_1::Warning",
"Area":"HMI_RT_1::Alarming",
"Name":"HMI_RT_1::AlarmTag_1:Discrete_alarm_1", "Priority":12}]}]}}
```

OnError
```
{"Message": "ErrorBrowseConfiguredAlarms", "ErrorCode": "<Code>",
"ErrorDescription": "<Description>", "ClientCookie": "Cookie>"}
```

For example:
```
{"Message": "ErrorBrowseAlarms", "ErrorCode": "-2165323798 /
-2165322773", "ErrorDescription": "Invalid system name.", or
"Your browse request has been expired", "ClientCookie":
"myBrowseAlarmsRequest1"}
```

BrowseAlarmClasses

Description

The command "`BrowseAlarmClasses`" returns the alarm classes of the local HMI system or all HMI systems communicating via Runtime Collaboration.

Information on the general browse behavior of the command can be found in section Behavior of the browse commands (Page 7751).

Request
```
{"Message": "BrowseAlarmClasses", "Params": {"Filter": <String>,
"Attributes"["<Attribute name>", ..., "<Attribute name>"],
"SystemNames": ["<Name>", ..., "<Name>"]}, "ClientCookie":
"<Cookie>"}
```

- `Filter`: Optional
  Restricts the command to alarm classes whose "Name" matches the filter.
  - Value: Filter string
    Permitted wildcards:

Wildcard	Description	Example
*	Replaces 0 to more characters	Filter string: "*Alarm" Alarm classes contained in the response: • "Alarm" • "SystemAlarm"
?	Replaces 1 character	Filter string: "Alarm_Prio_? Alarms contained in the response: • "Alarm_Prio_1" • "Alarm_Prio_2"

  - Default value: All alarm classes of the system specified by `SystemNames` are queried.
- `Attributes`: Optional
  Controls which attributes of the alarm class return the response:
  - Value: Comma-separated enumeration of attributes
    The response returns "Name" and "StateMachine" as well as the specified attributes.
  - Value: "*"
    The response returns the following attributes: Name, StateMachine, ID, Priority, NormalStateTextColor, NormalStateBackColor, RaisedStateTextColor, RaisedStateBackColor, RaisedStateFlashing, AcknowledgedStateTextColor, AcknowledgedStateBackColor, AcknowledgedStateFlashing, ClearedStateTextColor, ClearedStateBackColor, ClearedStateFlashing, AcknowledgedClearedStateTextColor, AcknowledgedClearedStateBackColor, AcknowledgedClearedStateFlashing
  - Default: The response returns "Name" and "StateMachine".
- `System`: Optional
  Controls from which system the tags are read.
  - Value: "*"
    All systems that communicate with each other via runtime collaboration
  - Value: Comma-separated list of systems that communicate with each other via runtime collaboration
    FOR EXAMPLE: "HMI_RT_1", "HMI_RT_2"
  - Default value: The local system

For example:

```
{"Message": "BrowseAlarmClasses", "Params": {"Filter":
"*Alarm*", "SystemNames": ["HMI_RT_1"]}, "ClientCookie":
"myBrowseAlarmClassRequest1"} //Browse for alarm classes in
specified system with filter
```

Response

OnSuccess

```
NotifyBrowseAlarmClasses <System>::<Alarm class> ...
<System>::<Alarm class>
```

For example:
```
NotifyBrowseAlarmClasses HMI_RT_1::Alarm
HMI_RT_1::SystemNotification HMI_RT_1::SystemInformation
HMI_RT_1::SystemAlarm HMI_RT_1::Notification
HMI_RT_1::OperatorInputInformation
```

OnError
```
ErrorBrowseAlarmClasses <Error description>
```

For example:
```
ErrorBrowseAlarmClasses Invalid arguments passed to browsing
function.
```

20.1.5.3 Reference

The following section contains a reference of the properties of alarms and tags that you get with the commands ReadAlarm and ReadTag.

The commands transfer the property values as string.

Tag properties

"Name" property

Name of the tag

"Value" property

Value of the tag at the moment of the read operation.

"Quality" property

Quality of the read operation of the tag

Possible values:

- "Good"
- "Bad"
- "Uncertain"

"QualityCode" property

Quality code of the read operation of the tag

"TimeStamp" property

Time stamp of the last successful read operation of the tag

"Error" property

Error code of the last read or write operation of the tag

"ErrorDescription" property

Description of the error code of the last read or write operation of the tag

Alarm properties

"InstanceID" property

InstanceID for an alarm with multiple instances

"SourceID" property

Source at which the alarm was triggered.

"Name" property

Name of the alarm

"AlarmClassName" property

Name of the alarm class

"AlarmClassSymbol" property

Symbol of the alarm class

"AlarmParameterValues" property

Parameter values of the alarm

"AlarmText1" ... "AlarmText9" properties

Additional texts 1-9 of the alarm

"ChangeReason" property

Trigger event of the modification of the alarm state

"Connection" property

Connection via which the alarm was triggered.

"State" property

Current alarm state

The property can contain the following values:

- "0": Normal
- "1": Raised
- "2": RaisedCleared
- "5": RaisedAcknowledged
- "6": RaisedAcknowledgedCleared
- "7": RaisedClearedAcknowledged
- "8": Removed

"StateText" property

Current alarm state as text, e.g. "active" or "inactive"

"EventText" property

Text that describes the alarm event.

"InfoText" property

Text that describes an operator instruction for the alarm.

"TextColor" property

Number with the text color of the alarm state

"BackColor" property

Number with the background color of the alarm state

"Flashing" property

Indicates whether the alarm flashes.

Values: "TRUE" or "FALSE"

"ModificationTime" property

Time of last modification to the alarm state

"RaiseTime" property

Trigger time of the alarm

"AcknowledgementTime" property

Time of alarm acknowledgment

"ClearTime" property

Time of alarm reset

"ResetTime" property

Time of alarm reset

"SuppressionState" property

Status of alarm visibility

"SystemSeverity" property

Severity of the system error

"Priority" property

Relevance for display and sorting of the alarm

"Origin" property

Origin for display and sorting of the alarm

"Area" property

Origin for display and sorting of the alarm

"Value" property

Current process value of the alarm

"ValueQuality" property

Quality of the process value of the alarm

"ValueLimit" property

Limit of the process value of the alarm

"UserName" property

User name of the operator control alarm

"HostName" property

Name of the host that triggered the alarm.

"ID" property

ID of the alarm that is also used in the display.

"AlarmGroupID" property

ID of the alarm group to which alarm belongs.

"SourceType" property

Source from which the alarm was generated, e.g. tag-based, controller-based or system-based alarm.

```
HmiAlarmSourceType SourceType { get; }
```

The enumeration "HmiAlarmSourceType" can contain the following values:

- `Undefined` (0)
- `Tag` (1)
- `Controller` (2)
- `System` (3)
- `Alarm` (4)

"DeadBand" property

Range of the triggering tag, in which no alarms are generated.

```
object DeadBand { get; }
```

"LoopInAlarm" property

Function that navigates from the alarm control to its origin.

```
string LoopInAlarm { get; }
```

"NotificationReason" property

Reason for the notification

The property can contain the following values:

- `"0": Unknown`
- `"1": Add`
  The alarm was added to the filtered result list. The alarm meets the filter criteria that apply to the monitoring.
- `"2": Modify`
  Properties of the alarm were changed, but the alarm is still part of the filtered result list.
- `"3": Remove`
  The alarm was part of the result list, but it no longer meets the filter criteria due to changes to its properties.

Note

Changes to the alarms will not result in notifications until the alarm again meets the filter criteria. In this case, "NotificationReason" is set to `Add`.

Note

Removing an alarm from business logic

The use case of the client determines whether the client ignores notifications via alarms with the "NotificationReason" `Modify` or `Remove`.

For example:

- State-based monitoring: The client wants to show a list of incoming alarms. All notification reasons are relevant. The client removes an alarm from the list as soon as the notification reason is `Remove`.
- Event-based monitoring: The client wants to send an email when an alarm comes in. Only the notification reason `Add` is relevant.

Example:

A customer application begins monitoring with the filter criterion "State" = 1. An alarm is triggered. Runtime notifies the customer application of the "NotificationReason" as follows:

NotificationReason	Description
Add	• The "State" property is 1. The alarm is active.
Modify	• The "State" property has not changed. • Another property that is not part of the filter criterion has changed, e.g. "Priority".
Remove	The "State" property has changed, e.g. alarm is inactive.

"Duration" property

Returns the time interval in nanoseconds between triggering of the alarm and its previous status change.

20.1.5.4 Syntax of the alarm filter

With an AlarmSubscription, a filter can be transferred so that not all active alarms of the alarm system are notified, but only those which match the filter. The filter syntax is based on SQL syntax. However, only the WHERE instruction is relevant. The keyword "WHERE" must be omitted.

Operators

The following operators can be used in the filter string of the alarm filter:

Operator	Description	Example
=	equal to	`Name = 'Recipe246'`
<>	not equal	`Value <> 0.0`
>	greater than	`Value > 25.0`
<	less than	`Value < 75.0`
>=	greater than or equal to	`Value >= 25.0`
<=	less than or equal to	`Value <= 75.0`
`OR, ||`	logical OR	`State = 1 OR State = 3`
`AND, &&`	logical AND	`Value >= 25.0 AND Value <= 75.0`
`BETWEEN`	within a range	`Value BETWEEN 25.0 AND 75.0`
`NOT BETWEEN`	outside a range	`Value NOT BETWEEN 25.0 AND 75.0`
`LIKE string`	corresponds to the string *string*	`Name LIKE 'Motor*'`
`NOT LIKE string`	does not correspond to the string *string*	`Name NOT LIKE 'Valve*'`
`IN (v1, v2, …)`	corresponds to one or more values	`State IN (1, 4, 7)`
`NOT IN (v1, v2, …)`	does not correspond to one or more values	`State NOT IN (0, 2, 3, 5, 6)`
`(…)`	brackets expressions	`Value <= 75.0 AND (State = 1 OR State = 3)`

Precedence of the operators:

Rank	Operators
1	• Relational operators: =, <>, >, <, >=, <= • LIKE • IN • BETWEEN
2	NOT
3	AND, &&
4	OR, ||

Permitted wildcards:

Wildcard	Description	Example
*	Replaces 0 to more characters	`Name LIKE 'Motor*'` `Reference = <1.*.15>1`
?	Replaces 1 character	`Name = 'Recipe?'`

20.2 Programming Custom Web Controls

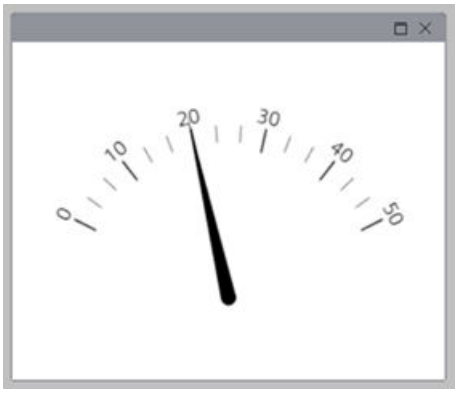
20.2.1 Custom web controls

Custom Web Controls represent an independent web page with interface to Runtime. Custom Web Controls offer you the option of adding your own elements to the visualization elements provided. Custom Web Controls thus extend usability and functionality to achieve an optimal visualization result.

Custom web controls are run on the web client and hosted in Runtime. A Custom Web Control can be displayed as an independent Web page in any browser and on any mobile device.

Note

Observe the performance limit of Unified Comfort Panels. We do not recommend using, for example, Custom Web Controls with 3D representations for Unified Comfort Panels.



Requirements for a web-based graphic interface

To use a Custom Web Control in WinCC, the Control must be anchored in a container. The container is provided on the user side by the Custom Web Control framework and contains components of the graphical user interface (GUI).

The following requirements apply when a web-based GUI component if it is to be provided in a Custom Web Control container:

- The component must be HTML5-based and interpretable by current browsers.
- The component must be executable exclusively on the client side.
- The component must work without interaction with client-side components outside the container.
- The component must comply with the principle of a Single Page Application (SPA) and fit on a web page. All code (HTML, JavaScript and CSS) must be received when the page is called or dynamically added during user actions. The web page may not reload at any time.
- The component must not know in which environment it is deployed. The component must be executable independent of the environment.
- All data exchange must take place through communication between client and server.

Application example

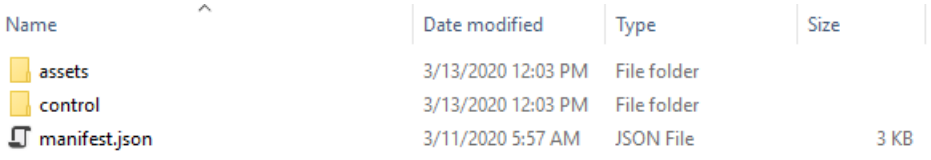
Based on an application example, you can learn more about the structure and development of a Custom Web Control: SIOS entry (https://support.industry.siemens.com/cs/ww/en/view/109779176).

20.2.2 General structure and folder structure

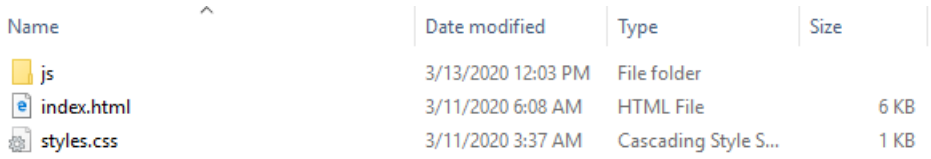
A ready-to-use Custom Web Control must be available as a "*.zip" file that contains all graphics and code files used. The structure is divided into two folders, "assets" and "control", and a "*.json" file (manifest.json).

The "assets" folder contains a logo that is displayed in the TIA Portal. The "control" folder contains "*.html", "*.js" and "*.css" files, as well as used graphics and icons that the Control needs for the display.

A Custom Web Control has the following folder structure:

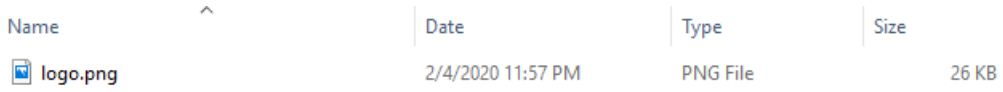


Contents of the "control" folder:



Name	Date modified	Type	Size
js	3/13/2020 12:03 PM	File folder	
index.html	3/11/2020 6:08 AM	HTML File	6 KB
styles.css	3/11/2020 3:37 AM	Cascading Style S...	1 KB

Contents of the "assets" folder:



Name	Date	Type	Size
logo.png	2/4/2020 11:57 PM	PNG File	26 KB

20.2.3 Contract-based interaction and the manifest file

20.2.3.1 Basics for the manifest

To enable the Unified Runtime server to communicate with the provided control, the control must reveal methods, events and properties to the Unified Runtime server.

The sum of the information that the control releases with it is called the "contract". For the custom web control container, this information is contained in a "*.json" file (manifest.json). The manifest file contains multiple sectors that each reveal elements to the container.

Tips for an efficient procedure

To verify that you have created a valid JSON file, use the notes in Visual Studio Code or copy the content of the file to an online validation tool, such as "https://jsonlint.com".

20.2.3.2 Manifest structure

Each manifest has two root elements:

- "mver": Specifies the manifest version.
- "control": Specifies the manifest type.

The "control" element provides the following sectors.

- "identity" sector
- "environment" sector
- "metadata" sector

- "contracts" sector
  The "contracts" sector contains the following:
  - Methods
  - Events
  - Properties
- "types" sector

"identity" sector

The "identity" sector contains identity information.

The following information of the data type "String" is required:

- "name": Defines the name of the Custom Web Control.
- "version": Defines the version of the Custom Web Control.
- "displayname": Defines the display name of the Custom Web Control.

  Note

  Special characters must not be used, e.g. #,$,*,%,.,/,;,?;[,],~,'".

- "icon" (optional)
  Includes the path for the logo that is displayed in the "Toolbox > My Controls" task card in the TIA Portal.
  The path can be specified as follows:
  - URL starting with "http://" or "https://"
  - Relative path to the storage location of the manifest starting with "./"
  - Data URL that contains a Base64 encoded image starting with "data:"

  The referenced image must be between 120x120 pixels and 320x320 pixels in size. The following image formats are supported:
  - JPG and JPEG
  - PNG
  - ICO
  - TIFF
  - BMP

  Use a square image to avoid distortions.
  If "icon" is not specified, only the display name ("displayname") is shown under "My Controls".

- "type": Each Custom Web Control can be referenced via the identity type and therefore requires a pre-defined structure. Types must follow the 8-4-4-4-12 pattern of a 128-bit integer (GUID).

  Note

  GUID generation

  For example, a GUID can be created as follows:
  - In Visual Studio under "Tools > Create GUID"
  - Under https://www.guidgenerator.com/ (https://www.guidgenerator.com/)

- "start" (optional): The start directory must be specified to set the starting point of the Custom Web Control for the browser.
  If this value is not defined, "./control/index.html" is used.

Example: "identity"

```
"identity": {
   "name": "GaugeMeter",
   "version": "1.0",
   "displayname": "GaugeMeter",
   "icon": "./assets/logo.ico",
   "type": "guid://551BF148-2F0D-4293-99C2-C9C3A1A6A073",
   "start": "./control/index.html"
}
```

"environment" sector

The optional "environment" sector provides information on the environment that is integrated into the Custom Web Control. If the sector does not exist, then no requirements and dependencies exist.

Requirements are specified under the element "prerequesites". "renderingspace" can be used below "prerequesites". Restrictions of the display of the Custom Web Control can be specified under "renderingspace".

The following restrictions are permitted:

Restriction	Data type	Description
minwidth	integer	Specifies the minimum width that is necessary to display the Custom Web Control.
maxwidth	integer	Specifies the maximum width that is permitted to display the Custom Web Control.
defaultwidth	integer	Specifies the default width of the Custom Web Control. The value must be between "minwidth" and "maxwidth".
minheight	integer	Specifies the minimum height that is necessary to display the Custom Web Control.

Restriction	Data type	Description
maxheight	integer	Specifies the maximum height that is permitted to display the Custom Web Control.
defaultheight	integer	Specifies the default height of the Custom Web Control. The value must be between "minheight" and "maxheight".
unit	string	Specifies the unit of the display restrictions. The following values are permitted: • "px" • "cm" • "mm" • "in" • "pt" If "unit" is not specified, "px" is used.

Extensions can be specified under "extensions".

Each extension has the following optional fields:

- "mandatory": Specifies whether the Custom Web Control can be used without the extension. Regardless of the value in this field, extensions of a Custom Web Control are always necessary.
- "version": Specifies a compatible version or versions.

You can find available extensions at Extensions (Page 7804).

Example: "environment"

```
"environment": {
  "prerequisites": {
    "renderingspace": {
      "defaultwidth": 450,
      "defaultheight": 300,
      "unit": "px"
    }
  }
  "extensions": {
    "HMI": {
      "mandatory": true,
      "version": "~1.0.0"
    }
  }
}
```

"metadata" sector

The following optional information can be stored, for example, as metadata:

- Author
- Keywords

- Description of the Custom Web Control
- Homepage

Metadata are not relevant for the execution of the Custom Web Control. User-defined metadata can be supplemented.

Example: "metadata"

```
"metadata":{
  "author": "Siemens",
  "keywords": [
    "Gauge",
    "GaugeMeter"
  ]
  "description": "Display tag value with a gauge."
"homepage": "https://www.siemens.com"
"company": "Siemens AG"
}
```

"contracts" sector

The "contracts" sector contains methods, events and properties as interface for use in the TIA Portal.

The Custom Web Control has access to methods, events and properties and therefore receives tag changes from the PLC, for example.

Data types can be used or referenced in this sector.

Note

A data type can be assigned with the keyword "type" below an element or it can be referenced with "$ref". The two keywords cannot be used at the same time.

You can find additional information at Data types and references in the manifest (Page 7800).

Note the following restrictions when naming methods, events, properties, arguments and parameters:

- Only alphanumeric characters of the ASCII character set and "_" are permitted.
- The names must not start with a number.
- The entry is case-sensitive.
- Special characters are not permitted.

Methods

"methods" contain a list of methods used by the Custom Web Control.

Methods of a Custom Web Control can be used in Unified Scripting to transfer information from the Unified server to the custom web control in the client. Methods are always executed asynchronously.

For example, a method to flash the passed zone can be called as follows:

```
Screen.Items('GaugeMeter_1').BlinkZone(2)
```

The following optional elements can be assigned to a method:

- "return": Specifies or references a data type.
  An additional "promise" field of the type "Boolean" returns whether the method is actually running asynchronously and is not fulfilled in a defined time period. The default value is "false". If the value is "true", the type specified with "return" is valid for the fulfilled value of the Promise object.
  You can react as follows to the Promise object:
  `"const result = await Screen.Items('GaugeMeter_1').BlinkZone(2) HMIRuntime.Trace(result);"`
- "parameters": Each parameter specifies or references a data type.
- "description": Specifies the description of the method.

Example: "methods"

```
"methods": {
  "BlinkZone": {
    "parameters": {
      "zoneIndex": {
        "type": "number"
      }
    },
    "description": "Let the given zone blink."
  }
}
```

Events

"events" contain a list of events used by the Custom Web Control.

Events are triggered by the Custom Web Control itself at any time. Events can be used in Unified Scripting to transfer information from the client to the server. They can be found in the engineering system under "Properties > Events".

An event can be assigned the following optional elements:

- "arguments": Contains arguments. Each argument specifies or references a data type.
- "description": Specifies the description of the event.

Example: "events"

```
"events": {
  "ZoneChanged": {
    "arguments": {
      "zoneIndex": {
        "type": "number"
      }
    },
    "description": "Whenever the zone is changed, this event is raised and
gives you the new zone index."
  }
}
```

Properties

"properties" contain a list of properties used by the Custom Web Control.

Properties can be found in the engineering system under "Properties > Properties > Interfaces".

The following elements can be assigned to a property:

- "type" or "$ref": A data type must be specified or referenced.

  Note

  Only individual elements can be connected

  When using complex data types, such as an array or user data types, only the elements of the bottom level can be linked to a property.

- "default" (optional): Specifies the default value of the property.
- "description" (optional): Specifies the description of the property.

Example: "properties"

```
"properties": {
  "GaugeValue": {
    "type": "number",
    "default": 20
    "description": "This property represents the value of the gauge."
  },
  "MinValue": {
    "type": "number",
    "default": 0
   "description": "This property represents the minimum value of the gauge."
  },
  "MaxValue": {
    "type": "number",
    "default": 50
   "description": "This property represents the maximum value of the gauge."
  },
}
```

"types" sector

The "types" sector contains local definitions for user-defined data types, objects and arrays.

A data type that is defined in this sector can only be referenced within this manifest. External data types from a JSON Schema can be referenced under "contract" or "types".

Example: "types"

```
"types": {
  "Color": {
    "$id": "http://tia.siemens.com/wincc-unified/types/s/color",
    "type": "number"
  },
  "AlignmentPart": {
    "type": "object",
    "properties": {
      "Vertical": {
        "$ref":"#/control/types/VerticalAlignment"
      }
    }
  },
  "VerticalAlignment": {
    "type": "string",
    "enum": [
      "Top",
      "Center",
      "Bottom"
    ],
    "default": "Center"
  }
}
```

See also

Creating the ZIP file (Page 7819)

20.2.3.3 Data types and references in the manifest

Data types

Data types in the "contracts" sector of the manifest can be specified or referenced as follows:

- As basic data type
  The following basic data types can be used without reference:
  - Boolean: Can accept "true" or "false".
  - Number: Any representable number, for example:
    Integer: 1; -3
    Float: 5.21
    Numbers in exponential format: 2.99792458e8
  - String: Any text
  - Null: Displays the zero object and is used as return type for methods without return value.
- As local reference to the "types" sector of the manifest
  Arrays, objects or user-defined data types can be defined in the "types" sector.
- As external reference to a JSON Schema that is offered by Siemens, for example:
  - "$id": "http://tia.siemens.com/wincc-unified/types/s/color"
  - "$id": "http://tia.siemens.com/wincc-unified/types/c/font"

User-defined data types are, for example, structured data types or basic data types with restrictions.

The following type restrictions are permitted in the manifest:

Type restriction	Description
enum	Specifies the permitted String values of an enumeration.
items	Specifies the permitted data type of an array.
minItems	Specifies the minimum number of elements in an array.
maxItems	Specifies the maximum number of elements in an array.
minimum	Specifies the minimum value of a number of the data type "number" or "integer".
maximum	Specifies the maximum value of a number of the data type "number" or "integer".
pattern	Specifies the permitted pattern as regular expression that defines the content of a string.
minLength	Specifies the minimum length of a string.
maxLength	Specifies the maximum length of a string.
required	Specifies a list of mandatory properties within a structure.

Identification of a data type

When you define a data type in the "types" sector, you can specify a Uniform Resource Identifier (URI) or a fragment in the optional "$id" field. This information uniquely identifies the data type across multiple manifests. Within the manifest in which a data type is defined, this data type can also be referenced by using its ID.

Note

Absolute URIs are preferred over fragments.

Referencing a data type

Data types in the "contracts" or "types" sector can be referenced with "$ref".

You have the following options for referencing data types:

- As reference to the "types" sector without using the "$id"
  Example: `"BackColor":{"$ref": "#/control/types/color"}`
- As reference to the "types" sector using the "$id"
  Example: `"BackColor":{"$ref": "http://tia.siemens.com/wincc-unified/types/s/color"}`

20.2.4 Interaction between control and container via the API

A single API object ("WebCC" object) is used to enable communication between the Custom Web Control and the Unified Runtime server.

The following requirements apply to this API object:

1. All functionalities that the Control needs for independent executability must be available on the client side.
2. The API object must be created and extended with the specific functionalities that the control provides through the manifest file.

The API object

The API object represents the interface through which the methods, events and properties of the Control are called or received from the framework.

For the initialization of the Custom Web Control, the properties, methods and events of the manifest file must be declared.

You can link the properties, methods and events to your code.

Note

Declaration

The name must match the name of the manifest file.

Note the following restrictions:

- Only alphanumeric characters of the ASCII character set and "_" are permitted.
- The names must not start with a number.
- The entry is case-sensitive.
- Special characters are not permitted.

Example: API object

```
{
  //Methods
  methods: {
    BlinkZone: function(zoneIndex){
      //code
    }
  },
  //Events
  events: ['ZoneChanged', 'Event2'],
  //Properties
  properties:{
    GaugeValue: " ",
    Property2: " "
  }
}
```

Integrating the "WebCC" object

Integrating the API object makes the corresponding namespaces available to the Custom Web Control.

As a requirement, a JavaScript file (webcc.min.js) must be integrated in "index.html", which performs a handshake between the control and the container.

CAUTION

Do not change "webcc.min.js" file

The "webcc.min.js" file is used to establish the connection and must not be changed.

The "index.html" file is the entry point of your web page.

Note

Download "webcc.min.js"

You can find the file "webcc.min.js" in the application example: SIOS entry (https://support.industry.siemens.com/cs/ww/en/view/109779176)

The "webcc.min.js" file contains the connection data to WinCC Unified.

After the connection setup, you can access the data that is defined in the "manifest.json" file from any position in your application.

Example: Integrating the "WebCC" object

```
<!doctype html>
<head>
  <script>…</script>
  <!-- Web Custom Control Facade -->
  <script type= text/JavaScript src='webcc.min.js'>
</head>
```

Initialization of the "WebCC" object

The API object must have been successfully initialized before the Control can be created. To check this, the tag "result" of the parameter "function(result)" is queried. It is used as an indicator and must supply "true" to continue. As an additional parameter, extensions can be called during initialization.

Example: Initialization of the "WebCC" object

```
WebCC.start( function( result ) {
      if ( result ) {
        //startup succeeded
        //add subscriptions
      } else {
        //startup failed
      }
    },
controlInit.ControlApi,
  ['HMI'] };
```

See also

Extensions (Page 7804)

20.2.5 Extensions

20.2.5.1 Basics of extensions

With extensions you can use additional functions in Custom Web Controls.

The following extensions can be used:

- HMI extension:
  - Obejct "WebCC.Extensions.HMI.Properties" provides access to all properties of the container that contains the Custom Web Control.
  - Object "WebCC.Extensions.HMI.Style" allows access to the active style
  - The "DatePrecise", "Big", and "Variant" prototypes as extensions to the integrated JavaScript objects.
- Formatting extension: The "WebCC.Extensions.Formatting.Output" object enables the formatting of text.
- Dialog extension: Allows access to a dialog window.

When using extensions, follow these steps:

1. You integrate the extensions used in the manifest in the "environment" sector.
   This permits the environment to check whether the respective extension exists.
2. You call the extensions used during the initialization of the "WebCC" object.
3. Call the extension as property of the "WebCC" object at any point in your Custom Web Control.

Integration in the manifest

Integrate extensions in the "environment" sector of the manifest as follows:

```
"environment": {
  "extensions": {
    "HMI": {
      "mandatory": true,
      "version": "~1.0.0"
    }
    "Formatting": {
      "mandatory": true,
      "version": "~1.0.0"
    }
    "Dialogues": {
      "mandatory": true,
      "version": "~1.0.0"
    }
  }
}
```

Initialization of the "WebCC" object

```
WebCC.start( function( result ) {
      if ( result ) {
        //startup succeeded
        //add subscriptions
      } else {
        //startup failed
      }
    },
controlInit.ControlApi,
  ['HMI', 'Formatting', 'Dialogues'] };
```

See also

Dialog extension (Page 7810)

Formatting extension (Page 7809)

HMI extension (Page 7805)

20.2.5.2 HMI extension

"Properties" object

The "WebCC.Extensions.HMI.Properties" object provides access to all properties of the container that contains the Custom Web Control. The properties are placed after the "Properties" object.

You can find all available properties in the WinCC Unified object model under AUTOHOTSPOT.

The extension enables the "WebCC.onPropertyChanged.subscribe" event that can be used to register for changes of properties.

"Style" object

The "WebCC.Extensions.HMI.Style" object has the "Name" property that contains the name of the active style.

The "WebCC.Extensions.HMI.Style.onChanged" event is initiated when the style is changed in runtime. The event contains the name of the style that is being activated.

Example

```
WebCC.Extensions.HMI.Style.onChanged.subscribe( function( currentStyle) {
console.log(currentStyle);
});
```

Data types

Introduction

Prototypes are provided as extension of the installed JavaScript objects; they are used in the HMI environment.

The prototypes are available in the global namespace.

"DatePrecise" prototype

The JavaScript object "Date" provides millisecond accuracy, while Unified Runtime works with nanosecond accuracy.

The "DatePrecise" object is used to work with nanosecond accuracy. The "DatePrecise" object does not contain any information about time zones and uses coordinated universal time (UTC) for calculations.

Constructors and methods

Constructor	Description
`DatePrecise()`	Creates a "DatePrecise" object for the current date and time.
`DatePrecise(year, month[, day[, hours[, minutes[, seconds[, milliseconds[, microseconds[, nanoseconds]]]]]]])`	Creates a "DatePrecise" object. This constructor corresponds to the JavaScript "Date" constructor, but enables additional parameters for microseconds and nanoseconds. The parameters "year" and "month" are mandatory.
`DatePrecise(DomHighResTimeStamp)`	Creates a "DatePrecise" object that accepts the "DomHighResTimeStamp" object of a browser with a millisecond value since January 1, 1970, and an accuracy in the microsecond range.
`DatePrecise([seconds, nanoseconds])`	Creates a "DatePrecise" object that accepts the second value since January 1, 1970, and an additional nanosecond offset.
`DatePrecise(date)`	Creates a "DatePrecise" object from a passed JavaScript "Date" object. The nanoseconds are "0".
`DatePrecise(precise)`	Creates a "DatePrecise" object from a passed "DatePrecise" object.

Method	Description
`getMicroseconds()`	Returns the number of microseconds (from 0 to 999).
`getNanoseconds()`	Returns the number of nanoseconds (from 0 to 999).
`getTime()`	Returns the number of milliseconds since January 1, 1970. This method corresponds to the method of the JavaScript "Date" object.

Method	Description
`getHrTime()`	Returns a precise date as an array with two numerical values. The first value represents the seconds elapsed since January 1, 1970. The second value is the offset in nanoseconds.
`setMicroseconds(microseconds)`	Sets the microseconds (from 0 to 999).
`setNanoseconds(nanoseconds)`	Sets the nanoseconds (from 0 to 999).
`setTime(DomHighResTimeStamp)`	Determines the date over a specific number of milliseconds, starting from January 1, 1970. This method corresponds to the method of the JavaScript "Date" object.
`setHrTime([seconds, nanoseconds])`	Specifies a precise date as array with two numerical values. The first value represents the seconds elapsed since January 1, 1970. The second value is the offset in nanoseconds.
`toDate()`	Returns a "Date" object. The nanosecond accuracy is lost.
`valueOf()`	Returns a "DomHighResTimeStamp" object. The nanosecond accuracy is lost. The object is compatible with the JavaScript "Date" object.

Examples

```
var ms = window.DatePrecise([1593862222, 545410000]).getTime();
var date = window.DatePrecise(Date.UTC(1960, 11, 24, 18, 4, 5, 10));
var jsdate = date.toDate();
```

"Big" prototype

The "Big" prototype enables processing of large numbers with any desired precision. You can find the library and application examples at "Big.js".

Constructors and methods

Note

The "n" parameter can take on the following data types:

- JavaScript data type "Number"
- "Big" data type
- "String" data type that contains a numerical value

Constructor	Description
`Big(n)`	Creates a number of the data type "Big" with the value "n".

Method	Description
`abs()`	Returns the absolute value of the "Big" number.
`cmp(n)`	Compares two "Big" numbers. The following return values occur: • If the "Big" number is greater than "n", 1 is returned. • If the "Big" numbers are the same, 0 is returned. • If the "Big" number is less than "n", -1 is returned.
`div(n)`	Returns the value of the "Big" number divided by "n".
`eq(n)`	Returns a Boolean value that indicates whether the "Big" number and "n" are the same.
`gt(n)`	Returns a Boolean value that indicates whether the "Big" number is greater than "n".
`gte(n)`	Returns a Boolean value that indicates whether the "Big" number is greater than or equal to "n".
`lt(n)`	Returns a Boolean value that indicates whether the "Big" number is less than "n".
`lte(n)`	Returns a Boolean value that indicates whether the "Big" number is less than or equal to "n".
`minus(n)`	Returns the value of the "Big" number minus "n".
`mod(n)`	Returns the value of the "Big" number using modulo of value "n".
`plus(n)`	Returns the value of the "Big" number plus "n".
`pow(exp)`	Returns the value of the "Big" number to the power of "exp". The value for "exp" must be an integer between -1e+6 and +1e+6.
`round([dp [, rm]])`	Returns the rounded value of the "Big" number to a maximum of "dp". The value for "dp" must be an integer between -1e+6 and +1e+6. The default value for the parameter "dp" is 20. The "rm" parameter supports the following modes: • 0: Rounded to zero. • 1: Rounded to the nearest neighbor. If the distance is equal, the figures are rounded up. • 2: Rounded to the nearest neighbor. If the distance is the same, it is rounded to the straight neighbor. • 3: Rounded up.
`sqrt()`	Returns the square root of the "Big" number.
`times(n)`	Returns the value of the "Big" number multiplied by "n".
`toExponential([dp])`	Returns a string that represents the value of the "Big" number type in exponential notation. The "dp" parameter defines the number of decimal places displayed. The value for "dp" must be an integer between 0 and 1e+6. The default value for the parameter "dp" is 20.
`toFixed([dp])`	Returns a string that represents the value of the "Big" number type in standard notation. The "dp" parameter defines the number of decimal places displayed. The value for "dp" must be an integer between 0 and 1e+6. The default value for the parameter "dp" is 20.

Method	Description
`toPrecise(sd)`	Returns a string that represents the number of significant digits of the "Big" number. The "sd" parameter defines the number of decimal places displayed. The value for "sd" must be between 1 and 1e+6. The default value for the parameter "sd" is 20. If the "Big" number has more than the number of significant digits defined by "sd", the return value is rounded to the number of significant digits defined by 'sd'. The rounding mode is 1.
`toString()`	Returns a string that represents the value of the "Big" number. Under the following conditions, the value is displayed in exponential notation: • The positive exponent is greater than or equal to 21. • The negative exponent is less than or equal to -7.

"Variant" prototype

Basic data types can be mapped with the "Variant" prototype.

Constructors and methods

Constructor	Description
`Variant(value, type)`	Creates a "Variant" object using any value and data type.

Methods	Description
`typeOf()`	Returns a numerical value that identifies the elementary data type.
`valueOf()`	Returns the value that was converted into the corresponding data types "Number", "Boolean", "String", "DataPrecise" or "Big". "Time" and "DateTime" are returned as values of the type "DatePrecise". Numerical values that cannot be mapped without loss of accuracy are returned as values of the type "Big".

Examples

```
var variant = window.Variant(47111, 0x5);
var big = variant.valueOf();
```

20.2.5.3 Formatting extension

The "WebCC.Extensions.Formatting.Output" object enables the creation and formatting of text according to the parameters passed.

Methods

Methods	Description
`format(value, pattern [, lcid])`	Takes any number or random text and formats it according to the parameters passed. The language can optionally be specified via the LCID. When the LCID is not transferred, the current language is used.

Example

```
var floatValue = WebCC.Extensions.Formatting.Output.format( 42.1111111, '{F2}', 'de-DE' );
//Ergebnis: 42,11
var hexValue = WebCC.Extensions.Formatting.Output.format( 45054, '{H,2}' );
//Ergebnis: AF FE
var dateValue = WebCC.Extensions.Formatting.Output.format( 1609745948315, '{D,@yyyy/MM/dd}
{T,@HH:mm:ss}');
//Ergebnis: 2021/01/04 07:39:08
```

Basics of extensions (Page 7804)

20.2.5.4 Dialog extension

The dialog extension enables you to open a dialog window that is not limited by the display range of the Control. A URL is made available to the user interface; it is displayed in the dialog. A JSON data model is also made available. It is transferred to the dialog and returned as soon as the dialog is closed.

The use of dialogs is asynchronous.

"WebCC.Extensions.Dialogues" object

The "WebCC.Extensions.Dialogues" object allows for the creation and use of one or more dialogs.

The object has the following methods and properties:

Methods	Description
`create(id, view, data, [options])`	Creates a "Dialog" object. The "id" parameter is transferred as a string. The "view" parameter is transferred as a string that contains a relative URL. The "data" parameter contains random data this is transferred to the dialog. The optional "options" parameter contains a JSON object with the following options: • Information on the size of the dialog box: "minwidth", "maxwidth", "minheight", "maxheight" and "unit". • A Boolean value "resizable" that defines whether the size of the dialog box can be changed. • A "caption" string that is displayed in the title of the dialog.
`list()`	Returns a string array that contains the IDs of currently created and opened dialog boxes. As soon as the dialog box is closed, the ID is no longer displayed in the string array.
`get(id)`	Returns a "Dialog" object with the transferred ID. If the ID does not exist, ZERO is returned.

Property	Description
`self`	The "self" property contains the "Dialog" object.

"WebCC.Extensions.Dialog" prototype

The "WebCC.Extensions.Dialog" prototype enables the interaction with the dialog instance and offers the following methods and events:

Methods	Description
`open(width, height)`	Creates a dialog and returns a "promise" property. If the dialog is already open, only the "promise" property is returned. The dialog is displayed in the current screen with the specified width and height.
`close([result])`	Closes a dialog and fulfills the associated "promise" property. The "result" parameter is optional and can be of any type. The "result" parameter normally contains the data that were transferred when the dialog was opened and were subsequently changed.
`cancel([reason])`	Closes a dialog. The "promise" property is rejected. The "reason" parameter is optional and can be of any type.

Property	Description
`id`	The "id" property contains the ID of the dialog. The ID is available as a string.
`promise`	The "promise" property contains information about the status of a dialog.
`data`	The "data" property contains the data that were transferred when a dialog was created.

Example: Opening a dialog

```
var dialog =  WebCC.Extensions.Dialogues.create('id_1','input.html',
'myData',
{ caption: 'GaugeValue', resizeable: false } );
if ( dialog ) {
  // open( width, height ) returns promise
  dialog.open( 250, 150 ).then(
    function success( data ) {
      // close called
      WebCC.Properties.GaugeValue = data;
      updateValue( data );
  }).catch(
    function ( reason ) {
      // cancel called
  });
}
```

Example: Access to data within a dialog

```
var self = WebCC.Extensions.Dialogues.self;
if ( self ) {
  // initialize dialog data
  var inputValue = self.data;
  // 'myData'
}
```

Example: Closing a dialog with fulfilled promise

```
var self = WebCC.Extensions.Dialogues.self;
if ( self ) {
  // close([result]) fullfill dialog promise
  self.close( data );
}
```

Example: Closing a dialog in case of cancellation

```
var self = WebCC.Extensions.Dialogues.self;
if ( self ) {
  // cancel([reason]) reject dialog promise
  self.cancel();
}
```

20.2.6 Revision of a graphical user interface

Introduction

User interfaces can be used as Custom Web Control by using the framework. This document is intended to describe the process by means of an example and uses a provided user interface. With this user interface, a slider controls the movement of a pointer.

The user interface can be found in the application example at the following address: SIOS entry (https://support.industry.siemens.com/cs/ww/en/view/109779176)

The code examples shown in this section can be found in the "index.html" file of the application example.

Conversion of the color coding

The TIA Portal and the manifest file use different color coding. The manifest file is not able to work with hexadecimal values, but only accepts decimal values. The author of the manifest file must convert the hexadecimal values as defined in the TIA Portal into decimal values.

To use a web page as a Custom Web Control, the encoding must be converted.

Example: Color coding

```
function toColor(num) {
  num >>>= 0;
  var b = num & 0xFF,
      g = (num & 0xFF00) >>> 8,
      r = (num & 0xFF0000) >>> 16,
      a = ((num & 0xFF000000) >>> 24) / 255;
  return 'rgba(' + [r, g, b, a].join(',') + ')';
}
```

Defining the default values of properties

Default properties are defined in the TIA Portal and for Runtime projects. These default properties define, among other things, font size, line thickness and value ranges. Default properties are obtained in Runtime during initialization of the setup.

Example: Defining default values

```
var defaultProperties = {
  GaugeValue: 20,
  GaugeBackColor: 4294967295,
  Alignment:
  {
    Vertical: 'Center'
  },
  LineThickness: 20,
  FontSize: 16,
  MinValue: 0,
  MaxValue: 50,
  DivisionCount: 5,
  Zones: [
    { Min: 0, Max: 30, StrokeColor: 4281381677 },
    { Min: 30, Max: 40, StrokeColor: 4294958336 },
    { Min: 40, Max: 50, StrokeColor: 4293934654 }
  ]
}
```

Initialization of the Custom Web Control

To be able to function as a Custom Web Control within WinCC, the "WebCC" object must be initialized. After that the Control can be created.

Initialization takes place in "index.html".

Initialization of the Custom Web Control

```
WebCC.start(
  // callback function; occurs when the connection is done or failed.
  // "result" is a boolean defining if the connection was successfull or
not.
  function (result) {
    if (result) {
      console.log('connected successfully');
      initializeGauge();
      // Set current values
      setProperty({ key: 'GaugeBackColor', value:
WebCC.Properties.GaugeBackColor });
      setProperty({ key: 'Alignment', value: WebCC.Properties.Alignment });
      setProperty({ key: 'LineThickness', value:
WebCC.Properties.LineThickness });
      setProperty({ key: 'DivisionCount', value:
WebCC.Properties.DivisionCount });
      setProperty({ key: 'FontSize', value: WebCC.Properties.FontSize });
      setProperty({ key: 'Zones', value: WebCC.Properties.Zones });
      setProperty({ key: 'MaxValue', value: WebCC.Properties.MaxValue });
      setProperty({ key: 'MinValue', value: WebCC.Properties.MinValue });
      setProperty({ key: 'GaugeValue', value:
WebCC.Properties.GaugeValue });
      // Subscribe for value changes
      WebCC.onPropertyChanged.subscribe(setProperty);
    }
    else {
      console.log('connection failed');
    }
  },
  // contract (see also manifest.json)
  {
    // Methods
    methods: {
     },
    // Events
    events: {
    },
    //Properties
    //////////
    properties: defaultProperties
  },
  // placeholder to include additional Unified dependencies (not used in
this example) [],
  // connection timeout
  10000
);
```

Operating the Control via WinCC

To operate the Custom Web Control via WinCC, some functions need to be implemented. The functions show an example of the use of the API object. The sequences of the functions are specific to this example, so they are not explained in detail.

Example: Operating the Control

```
// Updates the value shown by the gauge whenever it is changed, e.g. by a
WinCC Unified tag or script.
// This function will be called by "setProperty" whenever the contract
property GaugeValue is changed.
// - value: number that contains the new value to be shown in the gauge
meter. function updateValue(value) {
  gauge.set(value);
  const newZoneIndex = gauge.options.staticZones.indexOf(
    gauge.options.staticZones.
      filter(zone => zone.min <= gauge.value && gauge.value <=
zone.max).pop()
  );
  if (newZoneIndex != currentZoneIndex) {
    currentZoneIndex = newZoneIndex;
    WebCC.Events.fire('ZoneChanged', newZoneIndex);
  }
}

// Updates the alignment of the whole gauge inside the control. You can
place it at the top, middle or bottom.
// This function will be called by "setProperty" whenever the user changes
the alignment.
// - alignment: object that contains an enum property "Vertical" that can be
either "Top", "Center" or "Bottom".
function updateAlignment(alignment) {
  const item = document.getElementById('gauge');
  let vertVal = '0';
  let topVal = '0';
  switch (alignment.Vertical) {
    case 'Top':
      break;
    case 'Center':
      topVal = '50%';
      vertVal = '-50%';
      break;
    case 'Bottom':
      topVal = 'inherit';
      break;
  }
  item.style.top = topVal;
  item.style.transform = 'translate(0,' + vertVal + ')';
}

// Updates the labels of the gauge. All labels have to be updated whenever
the DivisionCount, MaxValue, MinValue or FontSize is changed.
// This function will be called by "setProperty" whenever one of those
contract properties change.
function updateLabels() {
  const labels = new Array(.Properties.DivisionCount).fill(0).map(
    (x, i) => (i + 1) * (WebCC.Properties.MaxValue -
WebCC.Properties.MinValue/WebCC.Properties.DivisionCount +
WebCC.Properties.MinValue
```

```
  );
  labels.unshift(WebCC.Properties.MinValue);
  gauge.setOptions({
    staticLabels: {
      font: WebCC.Properties.FontSize + 'px "Siemens Sans"',
      labels: labels
    }
  });
}

// Paints the given zones inside the gauge. This function will be called by
"setProperty" whenever a zone is changed or
// zones will be added or removed.
// - zones: array of new zones to be painted
function updateZones(zones) {
  gauge.setOptions({
    staticZones: zones.map(item => {
      return { strokeStyle: toColor(item.StrokeColor), min: item.Min, max:
item.Max };
    })
  });
}

// This is a callback function that is called every time a contract property
changes. The function forwards the change to
// other functions so you can see the new value in the control.
// - data: object containing a key and a value property. The "key" contains
the name of the changed contract property and the "value" contains the new
value.
function setProperty(data) {
  // console.log('onPropertyChanged ' + data.key); // uncomment this line
to check whether data is incoming in the browser console from WinCC Unified
  switch (data.key) {
  case 'GaugeValue':
    updateValue(data.value);
    break;
  case 'GaugeBackColor':
    document.body.style.backgroundColor = toColor(data.value);
    break;
  case 'Alignment':
    updateAlignment(data.value);
    break;
  case 'LineThickness':
    gauge.setOptions({ lineWidth: data.value / 100 });
    break;
  case 'FontSize':
    updateLabels();
    break;
  case 'MinValue':
    gauge.setMinValue(data.value);
    updateLabels();
    break;
  case 'MaxValue':
    gauge.maxValue = data.value;
    updateLabels();
```

```
    break;
  case 'DivisionCount':
    updateLabels();
    break;
  case 'Zones':
    updateZones(data.value);
    break;
  }
}

// Let the given zone blink by descreasing and increasing the alpha value of
the zone color from 0% to 100% and back to original value 2 times.
// - zoneIndex: integer as index of the zone that will blink.
function blinkZone(zoneIndex) {
  const currentZone = gauge.options.staticZones[zoneIndex];
  const rgba = currentZone.strokeStyle.split(',');
  const originalRgba = Number(rgba[3].replace(')', ''));
  let currentRgba = originalRgba;
  let state = 0; // 0: falling, 1: raising, 2: falling again
  let currentRound = 0;
  const timerId = setInterval(() => {
    switch (state) {
      case 0:
        currentRgba -= 0.2;
        if (currentRgba <= 0) {
          currentRgba = 0;
          state = 1;
        }
        break;
      case 1:
        currentRgba += 0.2;
        if (currentRgba >= 1) {
          currentRgba = 1;
          state = 2;
        }
        break;
      case 2:
        currentRgba -= 0.2;
        if (currentRgba < originalRgba) {
          currentRound++;
          if (currentRound >= 2) {
            clearInterval(timerId);
            return;
          } else {
            currentRgba = originalRgba;
            state = 0;
          }
        }
        break;
    }  rgba[3] = currentRgba.toFixed(1);
    currentZone.strokeStyle = rgba.join(',') + ')';
    gauge.setOptions(gauge.options.staticZones);
  }, 50);
}
```

20.2.7 Creating the ZIP file

To use the Custom Web Control, the hierarchy of folders and files must be compressed. The data must be available in compressed form. To create the file, you can use any application that can generate a valid file with the extension ".zip".

The name of the ZIP file must match the GUID, for example, "{551BF148-2F0D-4293-8E10-C9C3A1A6A073}.zip".

Note

GUID generation

For example, a GUID can be created as follows:

- In Visual Studio under "Tools > Create GUID"
- Under https://www.guidgenerator.com/ (https://www.guidgenerator.com/)

20.2.8 Restrictions

Unified Comfort Panel

When you make the Custom Web Control available on a Unified Comfort Panel, note the following special features:

- The Custom Web Control is executed locally without being hosted in a web server.
- Links outside of the Custom Web Control are not supported, e.g. http links.
- The retrieval of external data or adding of contents is not supported, for example, via the "XMLHttpRequest" object or "fetch".
- Debugging of the Custom Web Control on the Unified Comfort Panel is not supported.

Tips for an efficient procedure

If you want to test whether your Custom Web Control can be executed on the Unified Comfort Panel, run the file "Index.html" locally on a PC without hosting the Custom Web Control in its own web server.

Rounding error

The JavaScript data type "Number" is a 64-bit floating point data type. For integer values, a secure display of up to 15 digits is possible before rounding errors occur.

Tags that use "DInt" or "Date", for example, can therefore lead to rounding errors when used in Custom Web Controls.

To avoid rounding errors, use the prototypes "Big" and "DatePrecise".

Logic operation of complex data types

When using complex types, such as an array or user data types, only the elements of the bottom level can be linked to a property.

Access of devices outside of the network

When the custom web control is accessed by a device outside of the network, it may not be possible to display or operate the Custom Web Control. In this case, access to the Custom Web Control depends on the network and security settings.

20.2.9 Installing and using Custom Web Controls

Custom Web Controls are freely-programmable and serve as a specific solution that goes beyond the functionalities of the toolbox provided. You can use Custom Web Controls like any other tool in the screens.

Requirement

- A project has been created.
- An HMI device has been created.
- A screen has been created.

Installing Custom Web Control

To install Custom Web Controls for a TIA Portal project, follow these steps:

1. Open the directory of your project.
2. Open the "UserFiles" subfolder.
3. Create a folder with the name "CustomControls".
4. Store the created program as *.zip file in the "CustomControls" folder.
5. In the TIA Portal, click on the "Update" button in the "Toolbox" > "My Controls" task card. The Custom Web Control is displayed in the "Toolbox" task card of the "Screens" editor.

Using Custom Web Control

1. Drag the Custom Web Control from the "Toolbox" > "My Controls" task card onto the screen.
2. Select the Control.
3. In the Inspector window, go to "Properties > Events".
4. Configure system functions or scripts for the events used in the Control.
5. In the Inspector window, go to "Properties > Properties > Interface".
6. Assign static values for the interface properties or dynamize the interface properties according your requirements.
   When dynamizing with tags, note that the Control's access to the tags is "Read only" by default.
   If you want the Control to change the values of the tags, remove the check mark.
7. Compile and load the Runtime project.

20.2.10 Updating Custom Web Controls

Introduction

After changing the properties for custom web controls or configuring new events, you can update custom web controls.

Updating custom web controls

If you have changed the properties for custom web controls or configured new events, you can update the custom web controls as follows:

1. Click the Update icon in the "My Controls" palette.
2. Custom web controls are updated.
3. A message appears in the Inspector window:
   - "The object '{0}' was updated successfully".
   - "The object '{0}' was updated successfully, but some properties have been lost due to incompatible changes to the interface."
   - "All objects are up to date". You have not changed any properties or alarms.

Note

The placeholder '{0}' stands for a unique and complete path on which the custom web control is stored.

Restrictions for the update

If you have opened a project as read-only, the update is not possible.

The following changes to the custom web control prevent the automatic update:

- Renaming properties or events
- Deleting properties or events
- Changing the data type

20.3 Runtime API

20.3.1 Basics

Task of the runtime API

Runtime API describes the open programming interface of WinCC Unified PC RT. With the Runtime API, you can use the internal functions of WinCC in your own applications. With an ODK client, you can read out all the objects of the runtime system and change their runtime attributes, for example, for tags or alarms.

The ODK is optimized for the processing of mass data when special objects are used, for example the reading or writing of 1000 tags in one pass.

Note

Siemens is not liable for and does guarantee the compatibility of the data and information transported via the API interfaces with third-party software.

We expressly point out that improper use of the API interface can result in data loss or production downtimes.

Requirement

- Programming environment is installed, e.g. MS Visual Studio
- WinCC Runtime Unified Scada RT is installed.

Application of C++ and .NET

The Runtime API makes all the interfaces available for the access to the runtime system in the languages C++ and C#.

Name-based addressing of objects

The objects of the Runtime system are addressed by their name and the full name path.

The name path of objects consists of several components and has the following syntax:

```
[SystemName::][ObjectName][.ElementPath][:SubElementName]
```

- `SystemName`
  Name of a Runtime systems (optional)
  If the "SystemName" is omitted, the object is searched for on the local runtime system.
- `ObjectName`
  Name of a tag or a structure

- `ElementPath`
  Element of a structure
- `SubElementName`
  Subelement of an object, e.g. alarm or logging tag of a tag.

Examples for access to different object types:

- Simple tag: `MyRTSystem::MySimpleTag`
- Structure tag: `MyRTSystem::Motor.Temperature`
- Alarm of a simple tag: `MyDiscreteTag:MyDiscreteAlarm`
- Alarm of a structure tag: `Motor.Temperature:MyAnalogAlarm`
- Logging tag: `MySimpleTag:MyLoggingTag`
- Connection: `MyRTSystem::MyHmiConnection`

20.3.2 Creating a minimal ODK client

Introduction

An ODK client uses the ODK API to access objects of the WinCC Unified system.

In the following, an ODK client is created for use of the Runtime API in the C# and C++ languages.

The programs only contain the most needed components of a simple client. They form the framework for all the subsequent runtime code examples in this documentation. See also section Code samples (Page 7832).

Note

You will find additional programming examples on the installation medium in the file "Support\Openness\Siemens.Unified.Openness_SDK_<version number>.zip" in the subdirectory"ODK\samples".

Requirement

- Development environment is installed.
- The ODK SDK was extracted locally on your computer. You will find the ODK SDK in the "Support\Openness" folder on the WinCC Unified DVD in the file "Siemens.Unified.Openness_SDK_<version number>.zip".

  Note

  If you create a C++ ODK client, you must set the system tag "PATH=C:\Program Files\Siemens\Automation\WinCCUnified\bin" and perform a restart.

Procedure C# client

1. Create a new .NET project in the development environment.
2. Carry out the following project settings:
   - Target framework is .NET 4.6.
   - ODK client is "Release" version for the x64 platform.
3. Create references to the following assembly: Siemens.Runtime.HmiUnified.Interfaces.dll (Copy Local = False)
   You will find the assembly in the local folder to which you have extracted Openness_SDK.zip, in the subfolder "ODK\bin".
4. Create a program with the following code:

```
using System;
using System.Collections.Generic;
using System.Linq;
using System.Text;
using System.Threading.Tasks;

using Siemens.Runtime.HmiUnified;

namespace Siemens.Runtime.HmiUnified.TestClient
{
    class Program
    {

        static void Main(string[] args)
        {
            try
            {
                using (IRuntime runtime = Runtime.Connect())
                {
                    //do runtime operations
                }
            }
            catch (Exception ex)
            {
                System.Console.WriteLine(string.Format("Exception occured
{0}", ex.Message));
            }
        }
    }
}
```

Procedure C++ client

1. Create a new C++ project in the development environment.
2. Set the following include directories for required headers:
   - <Local folder to which you have extracted the ODK SDK>\ODK\include\ODK
   - <Local folder to which you have extracted the ODK SDK>\ODK\include\ODK\include\CF

3. Create references to the following libraries in "<Local folder to which you have extracted the ODK SDK>\ODK\include\ODK\lib":
   - HmiUnifiedRt.lib
   - CfCore.lib
4. Create a reference to the following directory as "Additional Library Directory":
   - <Local folder to which you have extracted the ODK SDK>\ODK\lib
5. Create a program with the following code:

```
#include <CfTL>

#include "IOdkRt.h"
#include "IOdkRtTag.h"
#include "IOdkRtTagLogging.h"
#include "IOdkRtAlarm.h"
#include "IOdkRtAlarmLogging.h"
#include "IOdkRtCpm.h"
#include "IOdkRtConnection.h"
#include "IOdkRtUmc.h"

#include <stdio.h>
#include <tchar.h>
#include <iostream>

using namespace Siemens::Runtime::HmiUnified;
using namespace Siemens::Runtime::HmiUnified::Common;
using namespace std;

int _tmain(int argc, _TCHAR* argv[])
{
    CCfString projectName = L"";
    IRuntimePtr pRuntime;

    if(CF_SUCCEEDED(Connect(projectName, &pRuntime)
    {
        // do runtime operations here
    }
    return 0;
}
```

Result

The program core of an ODK client is created.

You can complete the program with the fragments from the following code examples for ODK-API.

20.3.3 Authorizing users

Introduction

Before the ODK client can be used, all users that run the ODK client must be authorized.

Note

Only authenticated users can access the data of a project over the Runtime API with an ODK client.

Requirement

WinCC Unified RT setup has been carried out completely on the Runtime computer.

Procedure

Add the user who corresponds to the logged-on Windows user on the Runtime computer to the Windows user group "SIMATIC HMI" in the Windows user management.

Result

When the ODK client is connected to the Runtime system, the logged-on Windows user is authenticated via the user management of the Runtime computer.

If one of the checks fails, the ODK client does not establish a connection (error: "Authentication error" or "User has no access right").

20.3.4 Startup and shutdown behavior of an ODK application

20.3.4.1 Autostart of an ODK application

You have the possibility of starting ODK applications automatically on start-up of the device.

Requirement

Runtime is configured in such a way that it automatically started on start-up of the device without a user having to be logged on. (Default setting)

Procedure

In the Windows Task Scheduler, create a task which starts the ODK application on start-up of the device.

Note

User Service Mode

To use the ODK application in Service Mode, configure the security options in the dialog "Create task" in such a way that a user does not have to be logged on for starting the task.

Under Windows 10 activate the option "Run whether user is logged on or not".

Result

The "Connect" method of IRuntime wait for a maximum of ten minutes after the start of the ODK application until the Runtime has started up.

20.3.4.2 Shutdown behavior

You have the option to be notified by the system on shutdown of Runtime, for example, to start cleanup work on the client.

For this purpose, subscribe the system tag "@SystemActivationState" for monitoring. "@SystemActivationState" signals whether Runtime is active and can have the following values:

- System startup in progress (1)
- System started (activated) (2)
- System stopped (3)
- System shutdown in progress (4)
- System restart in progress (5)

Value 4 is the trigger to start cleanup work.

Note

Interface calls on shutdown

Do not call any functions of the ODK interfaces while the system is shut down.

20.3.4.3 Restart behavior

Tags subscribed for monitoring

After Runtime is restarted, you can continue to use the existing subscriptions.

20.3.5 Syntax of the alarm filter

With an AlarmSubscription, a filter can be transferred so that not all active alarms of the alarm system are notified, but only those which match the filter. The filter syntax is based on SQL syntax. However, only the WHERE instruction is relevant. The keyword "WHERE" must be omitted.

Operators

The following operators can be used in the filter string of the alarm filter:

Operator	Description	Example
`=`	equal to	`Name = 'Recipe246'`
`<>`	not equal	`Value <> 0.0`
`>`	greater than	`Value > 25.0`
`<`	less than	`Value < 75.0`
`>=`	greater than or equal to	`Value >= 25.0`
`<=`	less than or equal to	`Value <= 75.0`
`OR, ||`	logical OR	`State = 1 OR State = 3`
`AND, &&`	logical AND	`Value >= 25.0 AND Value <= 75.0`
`BETWEEN`	within a range	`Value BETWEEN 25.0 AND 75.0`
`NOT BETWEEN`	outside a range	`Value NOT BETWEEN 25.0 AND 75.0`
`LIKE string`	corresponds to the string *string*	`Name LIKE 'Motor*'`
`NOT LIKE string`	does not correspond to the string *string*	`Name NOT LIKE 'Valve*'`
`IN (v1, v2, …)`	corresponds to one or more values	`State IN (1, 4, 7)`
`NOT IN (v1, v2, …)`	does not correspond to one or more values	`State NOT IN (0, 2, 3, 5, 6)`
`(…)`	brackets expressions	`Value <= 75.0 AND (State = 1 OR State = 3)`

Precedence of the operators:

Rank	Operators
1	• Relational operators: =, <>, >, <, >=, <= • LIKE • IN • BETWEEN
2	NOT
3	AND, &&
4	OR, ||

Permitted wildcards:

Wildcard	Description	Example
*	Replaces 0 to more characters	`Name LIKE 'Motor*'` `Reference = <1.*.15>1`
?	Replaces 1 character	`Name = 'Recipe?'`

20.3.6 Locale IDs of the supported languages

At the AlarmSubscription, there is a Language property which defines the language of the alarm filter and the language of the alarm texts. In this case, a locale ID from the table below must be entered.

The following table contains the Microsoft locale IDs of the languages supported in the TIA Portal:

Language	Country/Region	Locale ID
Afrikaans	South Africa	1078
Albanian	Albania	1052
Armenian	Armenia	1067
Azerbaijani (Cyrillic)	Azerbaijan	2092
Azerbaijani (Latin)	Azerbaijan	1068
Basque	Basque country	1069
Belarusian	Belarus	1059
Bulgarian	Bulgaria	1026
Chinese	Chinese (Hong Kong S.A.R.)	3076
Chinese	Chinese (Macao S.A.R.)	5124
Chinese	Chinese (Singapore)	4100
Chinese	Chinese (Taiwan)	1028
Chinese	Chinese (PR China)	2052
Danish	Denmark	1030
German	Germany	1031
German	Liechtenstein	5127
German	Luxembourg	4103
German	Austria	3079
German	Switzerland	2055
English	Australia	3081

Language	Country/Region	Locale ID
English	Belize	10249
English	United Kingdom	2057
English	Ireland	6153
English	Jamaica	8201
English	Canada	4105
English	Caribbean	9225
English	New Zealand	5129
English	Philippines	13321
English	Zimbabwe	12297
English	South Africa	7177
English	Trinidad and Tobago	11273
English	USA	1033
Estonian	Estonia	1061

Language	Country/Region	Locale ID
Uzbek (Latin)	Uzbekistan	1091
Vietnamese	Vietnam	1066

20.3.7 Code samples

ODK is supplied with code samples for using the Runtime interfaces. Open the local folder to which you have extracted the file "Support\Openness\Siemens.Unified.Openness_SDK_<version number>.zip".

You will find the code samples in the subfolder "\ODK\samples".

Using the code samples in the help

To reduce the complexity of the code samples and enable better readability, the examples in the help deliberately exclude troubleshooting and freeing up memory.

The application programmer must add these elements during programming.

Constructs affected under C#

- Exception handling with try...catch...finally

```
try
{
   …
}
catch (Exception ex)
{
   …
}
finally
{
}
```

- Freeing up memory with Dispose or using (...)
  See also section Releasing objects (Page 7833).

For a description of how to evaluate ODK-specific errors, see section Error-handling interfaces (Page 7841).

Constructs affected under C++

- Methods for outputting error information
  For an example of implementation of the printErrorInformation method, see section IErrorInfo (Page 8001).
- Freeing up allocated memory
- Null pointer check: `if (pObject != nullptr) {…}`
- Error code check: `if (CF_SUCCEEDED(errorCode) {…}`

For a description of how to evaluate ODK-specific errors, see section Error codes of the C++ interfaces (Page 7986).

20.3.8 Description of the C# interfaces

20.3.8.1 Releasing objects

Creating objects with GetObject

In .NET-ODK, you create the objects with the "GetObject" method, for example:

```
ITagSet odkTagSet = runtime.GetObject<ITagSet>();
```

Memory is created internally for the object. In .NET, the Garbage Collector automatically releases the memory when an object is no longer needed. However, the memory is released at an indefinite time.

Note

The indefinite execution of the Garbage Collector may cause the memory to increase and appear as if it is not being released again. The real reason for this is that the Garbage Collector has not yet started!

Releasing objects created with GetObject

The ODK client should release the memory of objects created using the "GetObject" method as soon as the object is no longer needed.

The following cases must be distinguished here:

- Using the objects by synchronous ODK methods
- Using the objects by asynchronous ODK methods

Example when using synchronous ODK methods

When releasing objects used by synchronous ODK methods, use the keyword `using`:

Copy code

```
try
{
    using (ITag myTag = runtime.GetObject<ITag>("Tag1"))
    {
        IProcessValue value = myTag.Read(HmiReadType.Cache);   // Reads synchronous
    }
}
catch (OdkException ex)
{
    System.Console.WriteLine(string.Format("OdkException occured {0}", ex.Message));
}
```

Example when using asynchronous ODK methods

When you release objects that are used by asynchronous ODK methods, you can use the "Dispose" method. This can be called in the callback method:

Copy code

```
ITagSet odkTagSet = runtime.GetObject<ITagSet>();
odkTagSet.Add(new string[] { "Tag1", "Tag2" });

// Assign callback function
odkTagSet.OnReadResult += odkTagSet_OnReadResult;
odkTagSet.ReadAsync();// Reads asynchronous

void odkTagSet_OnReadResult(ITagSet sender, IList<IProcessValue> values, bool completed)
{
    try
    {
        …
    }
    catch (OdkException ex)
    {
        …
    }
    finally
    {
        if (null != sender)
        {
            sender.Dispose(); // Release memory
        }
    }
}
```

20.3.8.2 Interfaces of the Runtime environment

IRuntime

Description

The C# interface "IRuntime" specifies properties and methods for handling the Runtime system. The "Connect" method of the "Runtime" class is called to establish the connection to the Runtime system.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Members "Runtime"

The class implements the following method:

"Connect" method

Checks whether valid licenses are available for the products installed on the Runtime device:

- Yes: Connects ODK application and Runtime project.
- No: Supplies an error code. Use the interfaces for error handling to query the error description (license missing, expired, etc.).

The method is overloaded:

- Connect to locally running Runtime project. Logged-on Windows user is authenticated.
  `IRuntime Connect()`
- Connect to locally running Runtime project. The logged-on Windows user is not authenticated; instead, the user is specified as a parameter.

  Note

  Can only be used in a future version!

  `IRuntime Connect(string userName, string password)`

  – `user`
    User name

  – `password`
    Password

- Connect to a specific Runtime project. Logged-on Windows user is authenticated.

  Note

  Can only be used in a future version!

  `IRuntime Connect(string value)`
  `value`
  Name of a Runtime project

- Connect to a specific Runtime project. The logged-on Windows user is not authenticated; instead, the user is specified as a parameter.

  Note

  Can only be used in a future version!

  `IRuntime Connect(string value, string userName, string password)`

  – `value`
    Name of a Runtime project

  – `user`
    User name

  – `password`
    Password

"Dispose" method

Enable Runtime system with all resources.

`void Dispose()`

Members "IRuntime"

The following properties and methods are specified in the interface:

"ProjectName" property

Name of the current project

Note

Can only be used in a future version!

```
string ProjectName { get; }
```

"UserName" property

Name of the logged-on user

```
string UserName { get; }
```

"Product" property

Return version information and installed options of the Runtime system as "IProduct" object.

```
IProduct Product { get; }
```

"GetObject" method

Create a new instance of an object type T in a project.

```
T GetObject<T>(params object[] parameters)
```

The object type T adopts the following values:

- `ITag`, `ITagSet` or `ITagSetQCD`
  Access to tags
- `IAlarm`, `IAlarmSet` or `IAlarmSubscription`
  Access to alarm system
- `ILoggedTag` or `ILoggedTagSet`
  Access to logging tags
- `IAlsrmLogging` or `IAlarmLoggingSubscription`
  Access to logged alarms
- `IUserManagement`
  Access to user management
- `IConnection` or `IConnectionSet`
  Access to connections

`parameters`
Optional: A name or array with names of objects of the respective object type

"GetOption" method

Return an installed option of the Runtime system as "IOption" object using the name.

```
IOption GetOption(string optionName)
```

`optionName`
Name of the installed option

Example

Initialize the ODK and establish a connection to the active project of the Runtime system.

Copy code

```
public static IRuntime runtime = null;

public void Connect()
{
    // Connect to running project
    runtime = Siemens.Runtime.HmiUnified.Runtime.Connect();
}
```

Initialize an "IProduct" object and output the technical product version of the Runtime system:

```
public void GetVersionInfo(IRuntime runtime)
{
    IProduct product = runtime.Product;
    IVersionInfo version = product.Version;
    System.Console.WriteLine(string.Format("Product version: {0}.{1}.{2}.{3}",
version.Major, version.Minor, version.ServicePack, version.Update));

    ...
}
```

Access a tag with the name "Tag1":

```
public void ReadSingleTagSync()
{
    ITag myTag = runtime.GetObject<ITag>("Tag1");
   //further tag processing
}
```

See also

IProduct (Page 7837)

IErrorResult (Page 7841)

IProduct

Description

The C# interface "IProduct" specifies properties for handling product information of the Runtime system.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Members

The following properties are specified in the interface:

"Options" property

Return installed options of the Runtime system as a list of "IOption" objects.

```
IList<IOption> Options { get; }
```

"Version" property

Return version structure of the Runtime system as "IVersionInfo" object.

```
IVersionInfo Version { get; }
```

Example

The version of the "IProduct" object is read out and iterated via the installed "IOption" objects:

Copy code

```
public void GetVersionInfo(IRuntime runtime)
{
   // Get product version
   IProduct product = runtime.Product;
   IVersionInfo version = product.Version;
   System.Console.WriteLine(string.Format("Product version: {0}.{1}.{2}.{3}",
version.Major, version.Minor, version.ServicePack, version.Update));
   if (product.Options.Count > 0)
   {
      foreach (IOption op in product.Options)
      {
         IVersionInfo opVersion = op.Version;
         // Iterate through options and get version
         System.Console.WriteLine(string.Format("Option name: {0}", op.Name));
         System.Console.WriteLine(string.Format("Option version: {0}.{1}.{2}.{3}",
opVersion.Major, opVersion.Minor, opVersion.ServicePack, opVersion.Update));
      }
   }
}
```

See also

IRuntime (Page 7834)

IOption (Page 7839)

IVersionInfo (Page 7840)

IOption

Description

The C# interface "IOption" specifies properties and methods for handling installed product options of the Runtime system.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Members

The following properties and methods are specified in the interface:

"Name" property

Name of an installed option of the Runtime system

```
String Name { get; }
```

"Version" property

Return version structure of an installed option of the Runtime system as "IVersionInfo" object.

```
IVersionInfo Version { get; }
```

"GetObject" method

Create new instance of an object type T of the option.

```
T GetObject<T>(params object[] parameters)
```

- `T`
  The value defines a specific object type of the option.
- `parameters`
  Optional: A parameter or array with parameters for the object type of the option

Example

Instantiate and use installed options with name "MyOptionName":

Copy code

```
public void GetOptionObject()
{
   //load option component by name
   IMyOption rtOption = (IMyOption)runtime.GetOption("MyOptionName");
   //create a instance of the option object IMyOptionObject
   IMyOptionObject optionObject = rtOption.GetObject<IMyOptionObject>();
   string strMethod = optionObject.MyMethod();
   string strProperty = optionObject.MyProperty;
}
```

See also

IProduct (Page 7837)

IVersionInfo (Page 7840)

IVersionInfo

Description

The C# interface "IVersionInfo" specifies properties for handling version information of the Runtime system.

Members

The following properties are specified in the interface:

"Major" property

Main version of the Runtime system or of an installed option

```
uint16 Major { get; }
```

"Minor" property

Minor version of the Runtime system or of an installed option

```
uint16 Minor { get; }
```

"ServicePack" property

Service pack of the Runtime system or of an installed option

```
uint16 ServicePack { get; }
```

"Update" property

Update version of the Runtime system or of an installed option

```
uint16 Update { get; }
```

Example

Information about the installed "IOption" options of the runtime system is output:

Copy code

```
public void GetVersionInfo(IRuntime runtime)
{
   // Get product version
   IProduct product = runtime.Product;
   IVersionInfo version = product.Version;
   System.Console.WriteLine(string.Format("Product version: {0}.{1}.{2}.{3}",
version.Major, version.Minor, version.ServicePack, version.Update));
   if (product.Options.Count > 0)
   {
      foreach (IOption op in product.Options)
      {
         IVersionInfo opVersion = op.Version;
         // Iterate through options and get version
         System.Console.WriteLine(string.Format("Option name: {0}", op.Name));
         System.Console.WriteLine(string.Format("Option version: {0}.{1}.{2}.{3}",
opVersion.Major, opVersion.Minor, opVersion.ServicePack, opVersion.Update));
      }
   }
}
```

IProduct (Page 7837)

IOption (Page 7839)

20.3.8.3 Error-handling interfaces

IErrorResult

Description

The C# interface "IErrorResult" specifies properties of error results in runtime.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Members

The following properties are specified in the interface:

"Error" property

Error code of an error

```
int32 Error { get; }
```

"Name" property

Name of the associated object of the data source

```
string Name { get; }
```

Example

Error output when writing a TagSet:

Copy code

```
public void WritePartlyNotExistingTagSetSync()
{
   ITagSet odkTagSet = runtime.GetObject<ITagSet>();
   odkTagSet.Add("Tag1", 1);
   odkTagSet.Add("Tag2", 2);
   odkTagSet.Add("NotExistingTag1", 1);
   odkTagSet.Add("NotExistingTag2", 2);

  IList<IErrorResult> writeResult = odkTagSet.Write();

   foreach (var result in writeResult)
   {
      System.Console.WriteLine(string.Format("Write tag '{0}' failed, error code {1}",
result.Name, result.Error));
   }
}
```

See also

IRuntime (Page 7834)

IErrorInfo (Page 7842)

IErrorInfo

Description

The C# interface "IErrorInfo" specifies methods and properties for handling error codes.

Members

The following properties and methods are specified in the interface:

"Error" property

Error code of an error

```
int32 Error { get; }
```

"GetErrorDescription" method

Output an error description for the error code.

```
string GetErrorDescription(uint32 Error)
```

`Error`
Error code that is passed by the ODK client.

See also

IErrorResult (Page 7841)

OdkException

Description

In the case of exceptions, the ODK triggers an OdkException in the .Net environment. The OdkException can be caught by try-catch blocks and evaluated.

The "OdkException" class inherits all properties and methods of the .NET class "Exception".

Members "OdkException"

The following objects and methods are also implemented in the "OdkException" class for all properties and methods of the .NET class "Exception".

"OdkException" method

- Trigger exception without alarm.
  `OdkException()`
- Trigger exception with alarm and error description.
  `OdkException(string message)`
  `message`
  Description of the error
- Trigger exception with alarm and error description. Trigger additional exception with reference to triggering exception.
  `OdkException(string message, Exception innerException)`
  - `message`
    Description of the error
  - `innerException`
    Triggering exception
- Trigger exception with serialized data.
  `OdkException(SerializationInfo info, StreamingContext context)`
  - `info`
    Serialized data of the exception
  - `context`
    Describes the origin or target of the serialized data.

"ErrorCode" property

Error code of the exception

```
UInt32 ErrorCode { get; }
```

"ErrorSubCategory" property

Subcategory of an error code

```
UInt32 ErrorSubCategory { get; }
```

Example

Exception handling using the example of optional components:

Copy code

```
public void GetOptionObject()
{
    //load option component by name
    IMyOption rtOption = (IMyOption)runtime.GetOption("MyOptionName");
    //create a instance of the option object IMyOptionObject
    IMyOptionObject optionObject = rtOption.GetObject<IMyOptionObject>();
    try
    {
        string strMethod = optionObject.MyMethod();
        string strProperty = optionObject.MyProperty;
    }
    catch (OdkException ex)
    {
        //It is an option error?
        if (ex.ErrorSubCategory == MyOptionConstants.MYOPTION_ERRORCATEGORY)
        {
            //Handle option specific error
            if (ex.ErrorCode == (uint)MyErrorCodes.E_UNKNOWN_NAME)
            {
                //get error description
                string errorDescription = ex.Message;
            }
        }
    }
}
```

20.3.8.4 Interfaces of the tags

IProcessValue

Description

The C# interface "IProcessValue" specifies properties and methods for values of process tags of the Runtime system. The "IProcessValue" interface provides values from the result of a read operation or monitoring.

Members

The following properties are specified in the interface:

"Name" property

Name of the tag

```
string Name { get; }
```

"Value" property

Value of the tag at the moment of the read operation.

```
object Value { get; }
```

"Quality" property

Quality code of the read operation of the tag.

```
uint32 Quality { get; }
```

"TimeStamp" property

Time stamp of the last successful read operation of the tag.

```
DateTime TimeStamp { get; }
```

"Error" property

Error code of the last read or write operation of the tag.

```
int32 Error { get; }
```

Example

Output properties of the "IProcessValue" object that is returned by the ITag.Read method:

Copy code

```
public void ReadSingleTagSync()
{
   var myTag = runtime.GetObject<ITag>("Tag1");
   var value = myTag.Read(HmiReadType.Cache); // Reads value from Cache
   Console.WriteLine("Name: {0} Timestamp: {1} Value: {2} Quality: {3}", value.Name, value.
TimeStamp, value.Value, value.Quality);
}
```

ITag (Page 7845)

ITagSet (Page 7848)

ITagSetQCD (Page 7855)

ITag

Description

The C# interface "ITag" specifies properties and methods for handling tags of the Runtime system.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

The methods trigger an exception in the case of an error.

Members

The following properties and methods are specified in the interface:

"Name" property

Name of the tag that is read with the "Read" method.

```
string Name { get; set; }
```

"Read" method

Read process value and properties of the tag synchronously from the Runtime system.

```
IProcessValue Read(HmiReadType type = HmiReadType.Cache)
```

`type`
The enumeration "HmiReadType" specifies the origin of the tag value:

- `HmiReadType.Cache` (default parameter): Reads the tag value from the tag image. If no subscription exists, the tag is subscribed.
- `HmiReadType.Device`: Reads the tag value directly from the AS. The tag image is not used.

"Write" method

Write process value of the tag synchronously in the Runtime system.

```
void Write(
     object value,
     HmiWriteType type = HmiWriteType.NoWait)
```

- `value`
  Value of the tag
- `type`
  The enumeration "HmiWriteType" specifies whether the method waits for the write operation to be completed:
  - `HmiWriteType.NoWait` (default parameter): Writes the tag value without waiting. Errors for the write operation are not detected.
  - `HmiWriteType.Wait`: Waits until the tag value is written in the AS. If an error occurs during the write operation, an exception is triggered.

"WriteQCD" method

Write process value with quality code of the tag synchronously in the Runtime system. The tag also has a freely definable time stamp. You can use this to acquire past external measured values, for example.

Note

Reaction to external tags

For external tags, the method only writes the tag value. The QualityCode and time stamp are set internally by the system.

```
void Write(
     object value,
     DateTime timeStamp,
     uint32 qualityCode,
     HmiWriteType type = HmiWriteType.NoWait)
```

- `value`
  Value of the tag
- `timeStamp`
  Time stamp of the tag
- `qualityCode`
  Quality code of the tag
- `type`
  The enumeration "HmiWriteType" specifies whether the method waits for the write operation to be completed:
  - `HmiWriteType.NoWait` (default parameter): Writes the tag value without waiting. Errors for the write operation are not detected.
  - `HmiWriteType.Wait`: Waits until the tag value is written in the AS. If an error occurs during the write operation, an exception is triggered.

"WriteWithOperatorMessage" method

Write process value of the tag synchronously in the runtime system and create operator input alarm. In addition to the reason, the operator input alarm contains the old and new value, the user and host names and the unit.

```
void WriteWithOperatorMessage(
     object value,
     string reason)
```

- `value`
  Value of the tag
- `reason`
  Reason for the value change for alarm

Example

Read and write tag synchronously:

```
public void ReadSingleTagSync()
{
   var myTag = runtime.GetObject<ITag>("Tag1");
   var value = myTag.Read(HmiReadType.Cache); // Reads value from Cache
   Console.WriteLine("Name: {0} Timestamp: {1} Value: {2} Quality: {3}", value.Name, value.
TimeStamp,value.Value, value.Quality);
}

public void WriteSingleTagSync()
{
   var odkTag = runtime.GetObject<ITag>("Tag1");
   var value = 5;
   odkTag.Write(value, HmiWriteType.NoWait);   // Writes value without waiting that value h
as been written to PLC
   var pvalue = odkTag.Read(HmiReadType.Cache);
}
```

See also

IProcessValue (Page 7844)

ITagSet (Page 7848)

ITagSet

Description

The C# interface "ITagSet" specifies properties, methods and events for optimized access to several tags of the Runtime system.

After initialization of the "ITagSet" object, you can execute read and write access to multiple tags in one call. Simultaneous access demonstrates better performance and lower communication load than single access to multiple tags.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

The methods trigger an exception in the case of an error.

Note

You have the option to enumerate via a TagSet and to access a special element via the name. This is useful if you want to change the value of a tag in the TagSet for a write operation. To write the values in the process image, a "Write" or "WriteAsync" method must first be called:

```
MyTagSet.Add("MyTag1", "MyTag2");
MyTagSet["MyTag1"] = 5; // Set value to 5 for write operation
MyTagSet.Write();
```

Members

The following properties, methods and events are specified in the interface:

"ContextId" property

Identification characteristics of a TagSet. If several TagSets are used to read tags, you can assign the response to the request via ContextId.

Default value -1: The ContextId is not used.

```
int32 ContextId { get; set; }
```

"Count" property

Number of tags of a TagSet list

```
int32 Count { get; }
```

"Add" method

Add tag to a TagSet.

Add tag with or without process value to the TagSet:

```
void Add(ICollection<string> tagNames)
```

`tagNames`
List with tag names for TagSet

or

```
void Add(string tagName, object value = null)
```

- `TagName`
  Name of the tag for TagSet
- `value`
  New value of the tag, default: No value

"Remove" method

Remove individual tag from a TagSet.

```
void Remove(string tagName)
```

`tagName`
Name of the tag that is removed from TagSet.

"Clear" method

Remove all tags from a TagSet.

```
void Clear()
```

"Read" method

Read process values and properties of all the tags of a TagSet synchronously from the Runtime system.

```
IList<IProcessValue> Read(HmiReadType type = HmiReadType.Cache)
```

`type`
The enumeration "HmiReadType" specifies the origin of the tag value:

- `HmiReadType.Cache` (default): Reads the tag values from the tag image. If no subscription exists, the tag is subscribed.
- `HmiReadType.Device`: Reads the tag values directly from the automation system. The tag image is not used.

"ReadAsync" method

Read process values and properties of all the tags of a TagSet asynchronously from the Runtime system.

```
void ReadAsync(HmiReadType type = HmiReadType.Cache)
```

`type`
The enumeration "HmiReadType" specifies the origin of the tag value:

- `HmiReadType.Cache` (default): Reads the tag values from the tag image. If no subscription exists, the tag is subscribed.
- `HmiReadType.Device`: Reads the tag values directly from the automation system. The tag image is not used.

"Write" method

Write process values of all tags of a TagSet synchronously in the Runtime system.

```
IList<IErrorResult> Write(HmiWriteType type = HmiWriteType.NoWait)
```

`type`
The enumeration "HmiWriteType" specifies whether the method waits for the write operation to be completed:

- `HmiWriteType.NoWait` (default): Writes the tag values without waiting. Errors for the write operation are not detected.
- `HmiWriteType.Wait`: Waits until the tag values are written in the automation system. The associated errors are written.

"WriteAsync" method

Write process values of all tags of a TagSet asynchronously in the Runtime system.

The method always has the `HmiWriteType.Wait` type and waits until the tag value has been written in the automation system. If an error occurs during the write operation, it is reported via the AsyncHandler.

```
void WriteAsync()
```

"WriteWithOperatorMessage" method

Write process values of all tags of a TagSet synchronously in the Runtime system and create operator input alarms. In addition to the reason, the operator input alarms contain the old and new value, the user and host names and the unit.

```
void WriteWithOperatorMessage(string reason)
```

`reason`
Reason for the value change for alarm

"Subscribe" method

Subscribe all tags of a TagSet asynchronously for cyclic monitoring of the process values.

Note

Tags from IO devices with the "Cyclic in operation" acquisition mode

For a tag with the acquisition mode "Cyclic in operation", the value stored in the process image when Subscribe is called might be outdated. OnAdd therefore only provides the QualityCode "uncertain". Only value changes made after the Subscribe call provide the current value and the QualityCode "good".

```
void Subscribe()
```

"CancelSubscribe" method

Cancel monitoring of all tags of a TagSet.

```
void CancelSubscribe()
```

"OnReadResult" event

After completion of the read operation of the "ReadAsync" method, the event calls an instance of the "OnReadResultHandler" delegate.

Declares the event and the event handler for asynchronous read operations.

```
event OnReadResultHandler OnReadResult
```

"OnWriteResult" event

After completion of the write operation of the "WriteAsync" method, the event calls an instance of the "OnWriteResultHandler" delegate.

Declares the event and the event handler for asynchronous write operations.

```
event OnWriteResultHandler OnWriteResult
```

"OnDataChanged" event

After a process value change of a monitored TagSet, the event calls an instance of the "OnDataChangedHandler" delegate.

Declares the event and the event handler for process value changes.

```
event OnDataChangedHandler OnDataChanged
```

"OnReadResultHandler" delegate

Specifies the signature of the event handling method for the "OnReadResult" event of a TagSet.

```
void OnReadResultHandler(
        ITagSet sender,
        IList<IProcessValue> values,
        bool completed)
```

- `sender`
  The read out "TagSet" object
- `values`
  Event data as a list of "IProcessValue" objects of the read tag
- `completed`
  Status of the asynchronous transfer:
  - True: All values of the TagSet are read.
  - False: Not all values of the TagSet are read yet.

"OnWriteResultHandler" delegate

Specifies the signature of the event handling method for the "OnWriteResult" event of a TagSet.

```
void OnWriteResultHandler(
        ITagSet sender,
        IList<IErrorResult> values,
        bool completed)
```

- `sender`
  The written "TagSet" object
- `values`
  Error during write operations of tags as "IErrorResult" object
- `completed`
  Status of the asynchronous transfer:
  - True: All values of the TagSet are written.
  - False: Not all values of the TagSet are written yet.

"OnDataChangedHandler" delegate

Specifies the signature of the event handling method for the "OnDataChanged" event of a TagSet.

```
void OnDataChangedHandler(
        ITagSet sender,
        IList<IProcessValue> values)
```

- `sender`
  The monitored "TagSet" object
- `values`
  Event data as a list of "IProcessValue" objects of the changed process values

Example

Read TagSet synchronously and write with change:

Copy code

```
public void ReadTagSetSync()
{
   var odkTagSet = runtime.GetObject<ITagSet>())
   odkTagSet.Add(new[] { "Tag1", "Tag2" });
   var values = odkTagSet.Read();
   foreach (var value in values)
   {
      Console.WriteLine("Name: {0} Timestamp: {1} Value: {2} Quality: {3}", value.Name,
value.TimeStamp, value.Value, value.Quality);
      // Get Type information
      PrintProcessValue(value);
   }
}

public void WriteTagSetSyncWithChange()
{
   var odkTagSet = runtime.GetObject<ITagSet>();
   odkTagSet.Add(new[] { "Tag1", "Tag2" });
   // Modify the value of a tag in the tagset and write
    odkTagSet["Tag1"] = 5;
    odkTagSet.Write();
}
```

Define functions for asynchronous write operations and define the monitoring of TagSets.

Monitor events "OnWriteResult" or "OnDataChanged" and call the event handling methods "odkTagSet_OnWriteComplete" or "odkTag_OnDataChanged" on occurrence:

Copy code

```
public void WriteTagSetAsync()
{
   var odkTagSet = runtime.GetObject<ITagSet>();
   odkTagSet.Add("Tag1", 1);
   odkTagSet.Add("Tag2", 2);
   // Assign callback function
   odkTagSet.OnWriteResult += OdkTagSet_OnWriteResult;
   odkTagSet.WriteAsync();
   _event.WaitOne();
   _event.Reset();
}

private void OdkTagSet_OnWriteResult(ITagSet sender, IList<IErrorResult> values, bool compl
eted)
{
   foreach (var value in values)
   {
      Console.WriteLine("Error = {0} Name = {1}", value.Error, value.Name);
   }
}

public void SubscribeTagSet()
{
   var odkTagSet = runtime.GetObject<ITagSet>();
   odkTagSet.Add(new[] { "Tag1", "Tag2" });
   // Assign callback function
   odkTagSet.OnDataChanged += OdkTagSet_OnDataChanged;
   odkTagSet.Subscribe();
   _event.WaitOne();
   _event.Reset();
   odkTagSet.CancelSubscribe();
}

public void OdkTagSet_OnDataChanged(ITagSet sender, IList<IProcessValue> pItems)
{
   foreach (var value in pItems)
      Console.WriteLine("Name: {0} Timestamp: {1} Value: {2} Quality: {3}", value.Name, val
ue.TimeStamp, value.Value, value.Quality);
}
```

IProcessValue (Page 7844)

ITag (Page 7845)

ITagSetQCD

Description

The C# interface "ITagSetQCD" specifies properties, methods and events for optimized writing of several tags of the Runtime system. The tags also have a freely definable time stamp and quality code. You can use this to acquire past external measured values, for example.

Note

Reaction to external tags

For external tags, the method only writes the tag value. The QualityCode and time stamp are set internally by the system.

After initialization of the "ITagSetQCD" object, you can have read access to multiple tags in one call. Simultaneous access demonstrates better performance and lower communication load than single access to multiple tags.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

The methods trigger an exception in the case of an error.

Note

You have the option to enumerate via a TagSet and to access a special element via the name. This is useful if you want to change the value of a tag in the TagSet for a write operation. To write the values in the process image, a "Write" or "WriteAsync" method must first be called:

```
MyTagSet.Add("MyTag1", "MyTag2");
MyTagSet["MyTag1"] = 5; // Set value to 5 for write operation
MyTagSet.Write();
```

Members

The following properties, methods and events are specified in the interface:

"ContextId" property

Identification characteristics of a TagSet. If several TagSets are used to read tags, you can assign the response to the request via ContextId.

Default value -1: The ContextId is not used.

```
int32 ContextId { get; set; }
```

"Count" property

Number of tags of a TagSet list

```
int32 Count { get; }
```

"Add" method

Add user-defined tag with process value, quality code and time stamp to the TagSet.

```
void Add(string tagName, object value, DateTime timeStamp, uint32
qualityCode)
```

- `TagName`
  Name of the tag for TagSet
- `value`
  New value of the tag
- `timeStamp`
  Time stamp of the tag
- `qualityCode`
  Quality code of the tag

"Remove" method

Remove individual tag from a TagSet.

```
void Remove(string tagName)
```

`tagName`
Name of the tag that is removed from TagSet.

"Clear" method

Remove all tags from a TagSet.

```
void Clear()
```

"Write" method

Write process values of all tags of a TagSet synchronously in the Runtime system.

```
IList<IErrorResult> Write(HmiWriteType type = HmiWriteType.NoWait)
```

`type`
The enumeration "HmiWriteType" specifies whether the method waits for the write operation to be completed:

- `HmiWriteType.NoWait` (default): Writes the tag values without waiting. Errors for the write operation are not detected.
- `HmiWriteType.Wait`: Waits until the tag values are written in the automation system. The associated errors are written.

"WriteAsync" method

Write process values of all tags of a TagSet asynchronously in the Runtime system.

The method always has the `HmiWriteType.Wait` type and waits until the tag value has been written in the automation system. If an error occurs during the write operation, it is reported via the AsyncHandler.

```
void WriteAsync()
```

"OnWriteComplete" event

After completion of the write operation of the "WriteAsync" method, the event calls an instance of the "OnWriteCompleteTagSetQCDHandler" delegate.

Declares the event and the event handler for asynchronous write operations with quality codes and time stamps.

```
event OnWriteCompleteTagSetQCDHandler OnWriteComplete
```

"OnWriteCompleteTagSetQCDHandler" delegate

Specifies the signature of the event handling method for the "OnWriteComplete" event of a TagSet with quality code and time stamps.

```
void OnWriteCompleteTagSetQCDHandler(
        ITagSetQCD sender,
        IList<IErrorResult> pItems)
```

- `sender`
  Source of the event
- `pItems`
  Error during write operations of tag as "IErrorResult" object

Example

Write TagSet with time stamp and quality code synchronously:

Copy code

```
public void WriteTagSetQCDSync()
{
    var odkTagSet = runtime.GetObject<ITagSetQCD>();
    odkTagSet.Add("Tag1", 1, DateTime.Now, 128);
    odkTagSet.Add("Tag2", 2, DateTime.Now, 128);
    var writeResult = odkTagSet.Write();
}
```

IProcessValue (Page 7844)

ITagSetQCDItem (Page 7858)

ITagSetQCDItem

Description

The C# interface "ITagSetQCDItem" specifies properties for user-defined values of tags in a TagSetQCD. You can use this to acquire past external measured values, for example.

Note

Reaction to external tags

For external tags, only the tag value is set. The QualityCode and time stamp are set internally by the system.

The objects "ITagSetQCDItem" are not used by the "ITagSetQCD" object and can also be edited with the methods of the "ITagSetQCD" interface.

Members

The following properties are specified in the interface:

"Name" property

Name of the tag

```
string Name { get; set; }
```

"Value" property

Tag value

```
object Value { get; set; }
```

"Quality" property

Quality code of the tag

```
int32 Quality { get; set; }
```

"TimeStamp" property

Time stamp of the tag

```
DateTime TimeStamp { get; set; }
```

See also

ITagSetQCD (Page 7855)

ILoggedTagValue

Description

The C# interface "ILoggedTagValue" specifies the properties that a logged process value of a logging tag has in the logging system.

An "ILoggedTagValue" instance is a pure data object. The instance encapsulates all properties of the logged process value. It represents a historical process value.

Members

The following properties are specified in the interface:

"Name" property

Name of the logging tag

```
string Name { get; set; }
```

"Value" property

The logged process value

```
object Value { get; set; }
```

"Quality" property

Quality code of the process value

```
int16 Quality { get; set; }
```

If the "ILoggedTagValue" instance has been added to the log by calling the "Write" method, "Quality" has the value "GOOD" (sub-status: "Unspecific", extended sub-status: "Manual input"). The "Source time" marker is set to "1".

"TimeStamp" property

Time stamp of the process value

```
DateTime TimeStamp { get; set; }
```

"Error" property

Error code of the process value

```
uint32 Error { get; }
```

"Flags" property

Context information from the read operation for the process value

```
HmiTagLoggingValueFlags Flags { get; set; }
```

The "HmiTagLoggingValueFlags" enumeration contains the following bit-by-bit-coded values:

- 0: `Extra`
  There are still additional values at the time of the process value.
- 2: `Calculated`
  Process value is calculated.

- 16: `Bounding`
  Process value is a limit value.
- 32: `NoData`
  No additional information available
- 64: `FirstStored`
  Process value is the first value stored in the logging system.
- 128: `LastStored`
  Process value is the last value stored in the logging system.

See also

ILoggedTag (Page 7860)

ILoggedTagSet (Page 7861)

ILoggedTag

Description

The C# interface "ILoggedTag" specifies properties and methods for the handling of logging tags of a logging system. A logging tag is represented by an "ILoggedTag" instance. The information on the logged process values of the logging tag is stored in "ILoggedTagValue" instances.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Members

The following properties and methods are specified in the interface:

"Name" property

Name of the logging tag

```
string Name { get; set; }
```

"Read" method

Synchronous read operation.

The method returns a list of the "ILoggedTagValue" instances of the logging tag whose time stamps are in the time period defined by the arguments.

```
IList<ILoggedTagValue> Read(DateTime begin, DateTime end, bool
boundingValue)
```

- `begin`
  Start date of the time period
- `end`
  End date of the time period
- `boundingValue`
  True, to additionally return high and low limits.

"Write" method

Synchronous read operation.

The method manually writes an "ILoggedTagValue" instance to the logging system. "Quality" of the instance receives the value "GOOD" (sub-status: "Unspecific", extended sub-status: "Manual input"). The "Source time" marker is set to "1".

Application example: While the connection to the logging system is interrupted, the process value of a tag that is being logged changes. The resulting "ILoggedTagValue" instance is cached. After the connection has been re-established, manually add the instance to the log by calling "Write".

```
void Write(ILoggedTagValue tag)
```

- `tag`
  The "ILoggedTagValue" instance to be logged

Example

Output process values of the logging tag "Tag1:Tag1Logging1" for a time period:

Copy code

```
public void ReadSingleTag()
{
   var tag = _runtime.GetObject<ILoggedTag>("Tag1:Tag1Logging1";
   var begin = DateTime.UtcNow.AddMinutes(-10);
   var end = DateTime.UtcNow;
   var values = tag.Read(begin, end, true);
   foreach (var v in values)
   {
      var pinfo = _runtime.GetObject<IErrorInfo>();
      Console.WriteLine();
      Console.WriteLine("Name: {0} Error:{1}", v.Name, pinfo.GetErrorDescription(error));
   }
}
```

See also

ILoggedTagValue (Page 7859)

ILoggedTagSet (Page 7861)

ILoggedTagSet

Description

The C# interface "ILoggedTagSet" specifies properties, methods and events for optimized access to a collection of "ILoggedTag" instances of a logging system.

After initializing an "ILoggedTagSet" instance, you can read or write multiple "ILoggedTag" instances in one call. Simultaneous access demonstrates better performance and lower communication load than single access to multiple logging tags.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Members

The following properties, methods and events are specified in the interface:

"ContextId" property

Identifier of an "ILoggedTagSet" instance. If several "ILoggedTagSet" instances are used to read logging tags, you can assign the response to the job via ContextId.

Default value -1: The ContextId is not used.

```
int32 ContextId { get; set; }
```

"Count" property

Number of "ILoggedTag" instances of the "ILoggedTagSet" instance

```
int32 Count { get; }
```

"Add" method

The method is overloaded:

- Add multiple "ILoggedTag" instances to the "ILoggedTagSet" instance:
  `void Add(ICollection<string> tagNames)`
  `tagNames`
  A collection with the names of the "ILoggedTag" instances
- Add a single "ILoggedTag" instance to the "ILoggedTagSet" instance
  `void Add(string tagName)`
  `tagName`
  Name of the "ILoggedTag" instance
- Add an "ILoggedTagValue" instance to the "ILoggedTagSet" instance:
  `void Add(ILoggedTagValue object)`
  `object`
  Reference of the "ILoggedTagValue" instance

"Remove" method

Remove individual logging tag from the "ILoggedTagSet" instance.

```
void Remove(string tagName)
```

`tagName`
Name of the logging tag that is removed.

"Clear" method

Remove all logging tags from an "ILoggedTagSet" instance.

```
void Clear()
```

"Read" method

Synchronous read operation.

Reads from all logging tags of the "ILoggedTagSet" instance the logged process values whose time stamp is in the time period defined by the arguments.

```
IList<ILoggedTagValue> Read(DateTime begin, DateTime end, bool
boundingValue)
```

- `begin`
  Start date of the time period
- `end`
  End date of the time period
- `boundingValue`
  True, to additionally return high and low limits.

"ReadAsync" method

Asynchronous read operation.

Reads from all logging tags of the "ILoggedTagSet" instance the logged process values whose time stamp is in the time period defined by the arguments.

```
void ReadAsync(DateTime begin, DateTime end, bool boundingValue)
```

- `begin`
  Start date of the time period
- `end`
  End date of the time period
- `boundingValue`
  True, to additionally return high and low limits.

"Subscribe" method

Subscribe all logging tags of an "ILoggedTagSet" instance asynchronously to update the process values when they change. When new process values are logged, they can be processed with the "OnDataChanged" event.

```
void Subscribe()
```

"CancelSubscribe" method

Revoke update of process values on change for all logging tags of an "ILoggedTagSet" instance.

```
void CancelSubscribe()
```

"Write" method

Synchronous write operation.

Writes the "ILoggingTagValue" instances added by call of "Add" to the logging system. "Quality" of the instance receives the value "GOOD" (sub-status: "Unspecific", extended sub-status: "Manual input"). The "Source time" marker is set to "1".

Errors during write operations are returned in a list with "IErrorResult" instances.

Application example: The connection to the archive server was interrupted. After the connection has been re-established, add multiple "ILoggedTagValue" instances cached in the PLC to the archive afterwards by calling "Write".

```
IList<IErrorResult> Write()
```

"WriteAsync" method

Asynchronous write operation.

Writes the "ILoggingTagValue" instances added by call of "Add" to the logging system. "Quality" of the instance receives the value "GOOD" (sub-status: "Unspecific", extended sub-status: "Manual input"). The "Source time" marker is set to "1".

Application example: The connection to the archive server was interrupted. After the connection has been re-established, add multiple "ILoggedTagValue" instances cached in the PLC to the archive afterwards by calling "Write".

```
void WriteAsync()
```

"OnReadComplete" event

After completion of the read operation of the "ReadAsync" method, the event calls an instance of the "OnReadCompleteTagSetHandler" delegate.

Declares the event and the event handler for asynchronous read operations.

```
event OnReadCompleteTagSetHandler OnReadComplete
```

"OnDataChanged" event

After a process value change of a monitored "ILoggedTagSet" instance, the event calls an instance of the "OnDataChangedTagSetHandler" delegate.

Declares the event and the event handler for process value changes.

```
event OnDataChangedTagSetHandler OnDataChanged
```

"OnReadCompleteTagSetHandler" delegate

Specifies the signature of the event handling method for the "OnReadComplete" event of an "ILoggedTagSet" instance.

```
void OnReadCompleteTagSetHandler(
        ILoggedTagSet sender,
        uint32 errorCode,
        IList<ILoggedTagValue> values,
        bool completed)
```

- `sender`
  Source of the event
- `errorCode`
  Error during asynchronous transfer
- `values`
  Event data as a list of "ILoggedTagValue" instances of the read logging tags
- `completed`
  Status of the asynchronous transfer:
  - True: All values of the "ILoggedTagSet" instance are read out.
  - False: All values of the "ILoggedTagSet" instance are not yet read out.

"OnDataChangedTagSetHandler" delegate

Specifies the signature of the event handling method for the "OnDataChanged" event of an "ILoggedTagSet" instance.

```
void OnDataChangedTagSetHandler(
        ILoggedTagSet sender,
        uint32 errorCode,
        IList<ILoggedTagValue> value)
```

- `sender`
  Source of the event
- `errorCode`
  Error during asynchronous transfer
- `value`
  Event data as a list of "ILoggedTagValue" instances with process values of the changed logging tags

Example

Read and output process values of logging tags of a specified period in the "ILoggedTagSet" instance "tagSet" asynchronously:

Copy code

```
public void ReadTagSetAsync()
{
    try
    {
        var begin = DateTime.UtcNow.AddHours(-1);
        var end = DateTime.UtcNow;
        var tagSet = _runtime.GetObject<ILoggedTagSet>();
        tagSet.OnReadComplete += TagSet_OnReadComplete;
        tagSet.Add("Tag1:Tag1Logging1");
        tagSet.Add("Tag2:Tag2Logging1");
        tagSet.ReadAsync(begin, end, true);
    }
    catch (OdkException ex)
    {
        Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}

private void TagSet_OnReadComplete(ILoggedTagSet sender, uint errorCode,
IList<ILoggedTagValue> values, bool completed)
{
    Print(values);
    sender.Dispose();
}
```

Output process values of logging tag "Tag1:Tag1Logging1" in case of change:

Copy code

```
public void SubscribeTagSet()
{
    try
    {
        ILoggedTagSet tagSet = _runtime.GetObject<ILoggedTagSet>();
        tagSet.Add("Tag1:Tag1Logging1");
        tagSet.OnDataChanged += tagSet_OnDataChanged;
        tagSet.Subscribe();
    }
    catch (OdkException ex)
    {
        Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}

void tagSet_OnDataChanged(ILoggedTagSet sender, UInt32 errorCode, IList<ILoggedTagValue>
values)
{
    Print(values);
    sender.Dispose();
}
```

ILoggedTag (Page 7860)

ILoggedTagValue (Page 7859)

ITags

Description

The C# interface "ITags" defines methods with which you can access configured tags.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Members

"Find" method

Supplies a collection with "ITagAttributes" instances of the specified tag.

```
ICollection<ITagAttributes>  Find(ICollection<string> SystemNames,
string Filter = null, UInt32 LanguageID = 0)
```

- `SystemNames`
  Collection of SystemNames on which the tags were configured.
- (Optional) `Filter`
  Filter by name of the tags to restrict the search.
  Supports searching with wildcards (*).
- (Optional) `LanguageID`
  Language code ID of filter

"FindAsync" method

For asynchronous searching for "ITagAttributes" instances of the specified tags.

```
void FindAsync(IList<string> SystemNames, string Filter = null,
UInt32 LanguageID = 0)
```

- `SystemNames`
  Collection of SystemNames on which the tags were configured.
- (Optional) `Filter`
  Filter by name of the tags to restrict the search.
  Supports searching with wildcards (*)
- (Optional) `LanguageID`
  Language code ID of filter

"OnTagAttributesRecieved" event

After completion of the "FindAsync" method, the event calls an instance of the "OnTagAttributesRead" delegate.

```
event OnTagAttributesRead OnTagAttributesRecieved;
```

"OnTagAttributesRead" delegate

Specifies the signature of the event handling method for the "OnTagAttributesReceived" event of an "ITagAttributes" instance.

```
public delegate void OnTagAttributesRead(ITags sender,
ICollection<ITagAttributes> tagAttributes, bool completed)
```

- `sender`
  Source of the event
- `tagAttributes`
  Event data as collection of "ITagAttributes" instances
- `completed`
  Status of the asynchronous transfer:
  - True: All tags have been read out.
  - False: Not all tags have been read out yet.

ITagAttributes

Description

The C# interface "ITagAttributes" defines properties of a tag.

Member

"Name" property

The name of the tag. Must be unique throughout the device.

```
string Name { get; }
```

"DisplayName" property

The display name of the tags

```
string DisplayName { get; }
```

"DataType" property

The data type of the tag

```
HmiDataType DataType { get; }
```

"Connection" property

The connection of the tag

The memory location of the tag in the controller is accessed via the connection.

```
string Connection { get; }
```

"AcquisitionCycle" property

The acquisition cycle of tags

If you configure a tag at an object, the acquisition cycle of the tag is displayed at the object.

```
string AcquisitionCycle { get; }
```

"AcquisitionMode" property

The acquisition mode of the tag

```
HmiAcquisitionMode AcquisitionMode { get; }
```

The enumeration "HmiAcquisitionMode" can contain the following values:

- Undefined (0)
- CyclicOnUse (1)
- CyclicContinous (2)
- OnDemand (3)
- OnChange (4)

"MaxLength" property

The length of the tags.

The length is only available with a string tag. The length is preset for structure tags and cannot be changed.

```
UInt32 MaxLength { get; }
```

"Persistent" property

The persistence of the tags

```
bool Persistent { get; }
```

"InitialValue" property

The start value of the tag

After Runtime starts, the tag retains the start value until an operator or the PLC changes the value.

```
object InitialValue { get; }
```

"InitialMaxValue" property

The start value for the event "On exceeding".

```
object InitialMaxValue { get; }
```

"InitialMinValue" property

The start value for the event "On falling below"

```
object InitialMinValue { get; }
```

"SubstituteValue" property

The substitute value of the tag

If the selected condition occurs, the tag is filled with the substitute value in runtime.

```
object SubstituteValue { get; }
```

"SubstituteValueUsage" property

The condition for using the substitute value of the tag

```
HmiSubstituteValueUsage SubstituteValueUsage { get; }
```

The enumeration "HmiSubstituteValueUsage" can contain the following values:

- None (0)
- InvalidValue (1)
- RangeViolation (2)
- InvalidValueOrRangeViolation (3)

ILoggingTags

Description

The C# interface "ILoggingTags" defines methods with which you can access configured logging tags.

The interface inherits the Dispose() method of the "IDisposable" interface of the .NET framework.

Members

"Find" method

Supplies a collection with "ITagAttributes" instances of the specified logging tag.

```
ICollection<ILoggingTagAttributes>  Find(IList<string> SystemNames,
string Filter = null, UInt32 LanguageID = 0)
```

- `SystemNames`
  Collection of SystemNames on which the tags were configured.
- (Optional) `Filter`
  Filter by name of the tags to restrict the search.
  Supports searching with wildcard (*).
  Example:
  `Tag1:*` Supplies all logging tags of "Tag1".
- (Optional) `LanguageID`
  Language code ID of filter

"FindAsync" method

For asynchronous searching for "ILoggingTagAttributes" instances.

```
void FindAsync(IList<string> SystemNames, string Filter = null,
UInt32 LanguageID = 0)
```

- `SystemNames`
  Collection of SystemNames on which the tags were configured.
- (Optional) `Filter`
  Filter by name of the tags to restrict the search.
  Supports searching with wildcard (*).
  Example:
  `Tag1.*`: Supplies all logging tags of "Tag1".
- (Optional) `LanguageID`
  Language code ID of filter

"OnLoggingTagAttributesReadReceived" event

After completion of the "FindAsync" method, the event calls an instance of the "OnLoggingTagAttributesRead" delegate.

```
event OnLoggingTagAttributesRead OnLoggingTagAttributesReadRecieved;
```

"OnLoggingTagAttributesRead" delegate

Specifies the signature of the event handling method for the "OnLoggingTagAttributesRead" event of an "ILoggingTags" instance.

```
public delegate void OnLoggingTagAttributesRead(ILoggingTags
sender, ICollection<ILoggingTagAttributes> tagAttributes, bool
completed);
```

- `sender`
  Source of the event
- `tagAttributes`
  Event data as collection of "ILoggingTagAttributes" instances
- `completed`
  Status of the asynchronous transfer:
  - True: All logging tags are read out.
  - False: Not all logging tags are read out yet.

ILoggingTagAttributes

Description

The C# interface "ILoggingTagAttributes" defines properties of a logging tag.

Member

"Name" property

The name of the tag

```
string Name { get; }
```

"DisplayName" property

The display name of the tags

```
string DisplayName { get; }
```

"DataType" property

The data type of the tag

```
HmiDataType DataType { get; }
```

20.3.8.5 Interfaces of the alarms

IAlarmResult

Description

The C# interface "IAlarmResult" specifies properties for accessing properties of active alarms of the Runtime system.

An "IAlarmResult" object is a pure data object which maps all properties of an active alarm.

Members

The following properties are specified in the interface:

"InstanceID" property

InstanceID for an alarm with multiple instances

```
uint32 InstanceID { get; }
```

"SourceID" property

Source at which the alarm was triggered.

```
string SourceID { get; }
```

"Name" property

Name of the alarm

```
string Name { get; }
```

"AlarmClassName" property

Name of the alarm class

```
string AlarmClassName { get; }
```

"AlarmClassSymbol" property

Symbol of the alarm class

```
string AlarmClassSymbol { get; }
```

"AlarmParameterValues" property

Parameter values of the alarm

```
IReadOnlyList<object> AlarmParameterValues { get; }
```

"AlarmText1" ... "AlarmText9" properties

Additional texts 1-9 of the alarm

```
string AlarmText1 { get; }
```

...

```
string AlarmText9 { get; }
```

"ChangeReason" property

Trigger event for modification of the alarm state

```
uint16 ChangeReason { get; }
```

"Connection" property

Connection via which the alarm was triggered

```
string Connection { get; }
```

"State" property

Current alarm state

```
HmiAlarmState State { get; }
```

The enumeration "HmiAlarmState" can contain the following values:

- Standard (0x00)
- Raised (0x01)
- RaisedCleared (0x02)
- RaisedAcknowledged (0x05)
- RaisedAcknowledgedCleared (0x06)
- RaisedClearedAcknowledged (0x07)
- Removed (0x80)

"StateText" property

Current alarm state as text, for example, "active" or "inactive"

```
string StateText { get; }
```

"EventText" property

Text that describes the alarm event.

```
string EventText { get; }
```

"InfoText" property

Text that describes an operator instruction for the alarm.

```
string InfoText { get; }
```

"TextColor" property

Text color of the alarm state

```
uint32 TextColor { get; }
```

"BackColor" property

Background color of the alarm state

```
uint32 BackColor { get; }
```

"Flashing" property

Indicates whether the alarm is flashing.

```
bool Flashing { get; }
```

"InvalidFlags" property

Identification of the alarm with invalid data

```
byte InvalidFlags { get; }
```

"ModificationTime" property

Time of the last modification to the alarm state

```
DateTime ModificationTime { get; }
```

"RaiseTime" property

Time the alarm was triggered

```
DateTime RaiseTime { get; }
```

"AcknowledgementTime" property

Time of alarm acknowledgment

```
DateTime AcknowledgementTime { get; }
```

"ClearTime" property

Time of alarm reset

```
DateTime ClearTime { get; }
```

"ResetTime" property

Time of alarm reset

```
DateTime ResetTime { get; }
```

"SuppressionState" property

Status of alarm visibility

```
byte SuppressionState { get; }
```

"SystemSeverity" property

Severity of the system error

```
UInt8 SystemSeverity { get; }
```

"Priority" property

Relevance for display and sorting of the alarm

```
UInt8 Priority { get; }
```

"Origin" property

Origin for display and sorting of the alarm

```
string Origin { get; }
```

"Area" property

Origin area for display and sorting of the alarm

```
string Area { get; }
```

"Value" property

Current process value of the alarm

```
object Value { get; }
```

"ValueQuality" property

Quality of the process value of the alarm

```
uint16 ValueQuality { get; }
```

"ValueLimit" property

Process value limit of the alarm

```
object ValueLimit { get; }
```

"UserName" property

User name of the operator input alarm

```
string UserName { get; }
```

"UserResponse" property

Expected or required user response to the alarm

```
byte UserResponse { get; }
```

"HostName" property

Name of the host that triggered the alarm.

```
string HostName { get; }
```

"Id" property

ID of the alarm that is also used in the display.

```
Uint32 Id { get; }
```

"AlarmGroupID" property

ID of the alarm group to which the alarm belongs.

```
UInt32 AlarmGroupID { get; }
```

"SourceType" property

Source from which the alarm was generated, for example, tag-based, controller-based or system-based alarm.

```
HmiAlarmSourceType SourceType { get; }
```

The enumeration "HmiAlarmSourceType" can contain the following values:

- `Undefined` (0)
- `Tag` (1)
- `Controller` (2)
- `System` (3)
- `Alarm` (4)

"DeadBand" property

Range of the triggering tag in which no alarms are generated.

```
object DeadBand { get; }
```

"LoopInAlarm" property

Function that navigates from the alarm control to its origin.

```
string LoopInAlarm { get; }
```

"NotificationReason" property

Reason for the notification

```
HmiNotificationReason NotificationReason { get; }
```

The enumeration "HmiNotificationReason" can contain the following values:

- `Unknown` (0)
- `Add` (1)
  The alarm was added to the filtered result list. The alarm meets the filter criteria that apply to the monitoring.
- `Modify` (2)
  Properties of the alarm were changed, but the alarm is still part of the filtered result list.
- `Remove` (3)
  The alarm was part of the result list, but it no longer meets the filter criteria due to changes to its properties.

Note

Changes to the alarms only lead to notifications again when the alarm meets the filter criteria again. In this case, "NotificationReason" is set to `Add`.

Note

Removing alarm from business logic

The use case of the client determines whether the client ignores notifications via alarms with the "NotificationReason" `Modify` or `Remove`.

For example:

- State-based monitoring: The client wants to show a list of incoming alarms. All notification reasons are relevant. The client removes an alarm from the list as soon as the notification reason is `Remove`.
- Event-based monitoring: The client wants to send an email when an alarm comes in. Only the notification reason `Add` is relevant.

Example:

An ODK client begins monitoring with the filter criterion "State" = 1. An alarm is triggered. Runtime notifies the ODK client of the "NotificationReason" as follows:

Notification-Reason	Description
Add	• The "State" property is 1. The alarm is active.
Modify	• The "State" property has not changed. • Another property that is not part of the filter criterion has changed, e.g. "Priority".
Remove	The "State" property has changed, for example, alarm is inactive.

"Duration" property

Returns the time interval in nanoseconds between triggering of the alarm and its previous status change.

```
TimeSpan  Duration { get; }
```

Example

When alarms become active, a selection of properties of the "IAlarmResult" objects is output:

Copy code

```
public void alarm_OnAlarmHandler(IAlarmSubscription sender, UInt32 nGlobalError, String
systemName, IList<IAlarmResult> value, bool completed)
{
    if (0 == nGlobalError)
    {
        try
        {
            AlarmList = new List<IALarmResult>();
            foreach (var item in value)
            {
               System.Console.WriteLine(string.Format("InstanceID: {0}", item.InstanceID));
                System.Console.WriteLine(string.Format("AcknowledgementTime: {0}",
item.AcknowledgementTime));
                System.Console.WriteLine(string.Format("AlarmClass: {0}",
item.AlarmClassName));
                System.Console.WriteLine(string.Format("AlarmClassSymbol: {0}",
item.AlarmClassSymbol));
                System.Console.WriteLine(string.Format("Id: {0}", item.Id));
                System.Console.WriteLine(string.Format("AlarmParameterValues: {0}",
item.AlarmParameterValues));
              System.Console.WriteLine(string.Format("AlarmText1: {0}", item.AlarmText1));
              System.Console.WriteLine(string.Format("AlarmText9: {0}", item.AlarmText9));
                System.Console.WriteLine(string.Format("Area: {0}", item.Area));
                System.Console.WriteLine(string.Format("BackColor: {0}", item.BackColor));
                System.Console.WriteLine(string.Format("ChangeReason: {0}",
item.ChangeReason));
                System.Console.WriteLine(string.Format("ClearTime: {0}", item.ClearTime));
              System.Console.WriteLine(string.Format("Connection: {0}", item.Connection));
                System.Console.WriteLine(string.Format("DeadBand: {0}", item.DeadBand));
                System.Console.WriteLine ("Duration: {0}", item.Duration);
                System.Console.WriteLine(string.Format("EventText: {0}", item.EventText));
                System.Console.WriteLine(string.Format("InfoText: {0}", item.InfoText));
                System.Console.WriteLine(string.Format("Flashing: {0}", item.Flashing));
                System.Console.WriteLine(string.Format("HostName: {0}", item.HostName));
                System.Console.WriteLine(string.Format("InvalidFlags: {0}",
item.InvalidFlags));
                System.Console.WriteLine(string.Format("LoopInAlarm: {0}",
item.LoopInAlarm));
                System.Console.WriteLine(string.Format("ModificationTime: {0}",
item.ModificationTime));
                System.Console.WriteLine(string.Format("Name: {0}", item.Name));
                System.Console.WriteLine(string.Format("Origin: {0}", item.Origin));
                System.Console.WriteLine(string.Format("Priority: {0}", item.Priority));
                System.Console.WriteLine(string.Format("RaiseTime: {0}", item.RaiseTime));
                System.Console.WriteLine(string.Format("ResetTime: {0}", item.ResetTime));
                System.Console.WriteLine(string.Format("SourceID: {0}", item.SourceID));
              System.Console.WriteLine(string.Format("SourceType: {0}", item.SourceType));
                System.Console.WriteLine(string.Format("State: {0}", item.State));
                System.Console.WriteLine(string.Format("StateText: {0}", item.StateText));
                System.Console.WriteLine(string.Format("SuppressionState: {0}",
item.SuppressionState));
                System.Console.WriteLine(string.Format("SystemSeverity: {0}",
item.SystemSeverity));
                System.Console.WriteLine(string.Format("TextColor: {0}", item.TextColor));
                System.Console.WriteLine(string.Format("User: {0}", item.UserName));
```

Copy code

```
                System.Console.WriteLine(string.Format("UserResponse: {0}",
item.UserResponse));
                System.Console.WriteLine(string.Format("Value: {0}", item.Value));
                System.Console.WriteLine(string.Format("ValueLimit: {0}",
item.ValueQuality));

                AlarmList.Add(item);
            }
            ...
        }
        ...
    }
}
```

See also

IAlarm (Page 7880)

IAlarmSubscription (Page 7895)

IAlarm

Description

The C# interface "IAlarm" specifies properties and methods for handling active alarms of the runtime system.

The methods trigger an exception in the case of an error.

Members

The following properties and methods are specified in the interface:

"Error" property

Error code of the alarm

```
uint32 Error { get; set; }
```

"Name" property

Name of the active alarm

```
string Name { get; set; }
```

"Acknowledge" method

Acknowledge active alarm or instance of an active alarm synchronously.

```
void Acknowledge(UInt32 instanceId)
```

- `instanceID`
  - Value "0": Acknowledge all instances of an active alarm.
  - Value > "0": Acknowledge instance with this ID.

"Disable" method

Deactivate generation of the alarm in the alarm source synchronously.

```
void Disable()
```

"Enable" method

Activate generation of the alarm in the alarm source again synchronously.

```
void Enable()
```

"Reset" method

Acknowledge the inactive state of an active alarm or an instance of an active alarm synchronously.

```
void Reset(UInt32 instanceId)
```

- `instanceID`
  - Value "0": Acknowledge the inactive state of the active alarm.
  - Value > "0": Acknowledge the inactive state of an instance with this ID.

"Shelve" method

Hide active alarm synchronously.

```
void Shelve()
```

"Unshelve" method

Display hidden alarm synchronously again.

```
void Unshelve()
```

Example

Acknowledge active alarm synchronously:

Copy code

```
public void AcknowledgeAlarms(IList<IAlarmResult> AlarmList)
{
    if (AlarmList != null)
    {
        foreach (var alarm in AlarmList)
        {
            var alarmAck = runtime.GetObject<IAlarm>(alarm.Name);
            alarmAck.Acknowledge((alarm.InstanceID); // to acknowledge a particular alarm
instance, parameter can be ommitted if all instances of an alarm shall be acknowledged.
        }
    }
}
```

IAlarmResult (Page 7872)

IAlarmSet (Page 7882)

IAlarmSubscription (Page 7895)

IAlarmSet

Description

The C# interface "IAlarmSet" specifies properties, methods and events for optimized access to several active alarms of the runtime system.

After the initialization of the "IAlarmSet" object, you can execute asynchronous operations with multiple alarms in one call, e. g. acknowledgment. Simultaneous access demonstrates better performance and lower communication load than single access to multiple tags.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

The methods trigger an exception in the case of an error.

Members

The following properties, methods and events are only specified in the interface:

Access operator "this[string]"

Accessing an element of an alarm set via the alarm name.

```
IAlarm this[string alarmName] { get; set; }
```

`alarmName`
Name of the alarm that is changed in the AlarmSet.

"Count" property

Number of alarms of an AlarmSet list.

```
int32 Count { get; }
```

"Add" method

Add an active alarm or an instance of the alarm to the AlarmSet.

```
IAlarm Add(string alarmName, UInt32 instanceId)
```

- `alarmName`
  Name of the alarm that is added to the AlarmSet.
- `instanceId`
  Value = "0": Add all instances of an active alarm.
  Value > "0": Add instance with this ID.

"Remove" method

Remove a single alarm or an instance of an alarm from the AlarmSet.

```
void Remove(string alarmName, UInt32 instanceId)
```

- `alarmName`
  Name of the alarm that is removed from the AlarmSet.
- `instanceID`
  value = "0": Remove all instances of an active alarm
  Value > "0": Remove instance with this ID.

"Clear" method

Remove all alarms from an AlarmSet.

```
void Clear()
```

"Acknowledge" method

Acknowledge alarms of the AlarmSet asynchronously.

```
int Acknowledge()
```

"Disable" method

Deactivate generation of alarms of the AlarmSet in the alarm source asynchronously.

```
void Disable()
```

"Enable" method

Activate generation of alarms of the AlarmSet in the alarm source again asynchronously.

```
void Enable()
```

"Reset" method

Acknowledge inactive state of the alarms of the AlarmSet asynchronously. This method is relevant for alarms with the state machine "Alarm with acknowledgment and confirmation". Other state machines do not require a reset.

```
void Reset()
```

"Shelve" method

Hide alarms of the AlarmSet asynchronously.

```
void Shelve()
```

"Unshelve" method

Show hidden alarms of the AlarmSet asynchronously again.

```
void Unshelve()
```

"OnAcknowledgeHandler" event

When an AlarmSet is acknowledged with the "Acknowledge" and "AckknowledgeInstance" methods, the event calls an instance of the "OnAlarmSetEventHandler" delegate.

Declares the event and the event handler for the asynchronous acknowledgment of the alarms.

```
event OnAlarmSetEventHandler OnAcknowledgeHandler
```

"OnResetHandler" event

When the inactive state of the alarms of an AlarmSet is acknowledged with the "Reset" method, the event calls an instance of the "OnAlarmSetEventHandler" delegate.

Declares the event and the event handler for the asynchronous removal of the alarms.

```
event OnAlarmSetEventHandler OnResetHandler
```

"OnDisableHandler" event

When the alarms of an AlarmSet are deactivated with the "Disable" method, the event calls an instance of the "OnAlarmSetEventHandler" delegate.

Declares the event and the event handler for the asynchronous deactivation of the alarms.

```
event OnAlarmSetEventHandler OnDisableHandler
```

"OnEnableHandler" event

When the alarms of an AlarmSet are reactivated with the "Enable" method, the event calls an instance of the "OnAlarmSetEventHandler" delegate.

Declares the event and the event handler for the asynchronous reactivation of the alarms.

```
event OnAlarmSetEventHandler OnEnableHandler
```

"OnShelveHandler" event

When the alarms of an AlarmSet are hidden with the "Shelve" method, the event calls an instance of the "OnAlarmSetEventHandler" delegate.

Declares the event and the event handler for the asynchronous hiding of the alarms.

```
event OnAlarmSetEventHandler OnShelveHandler
```

"OnUnshelveHandler" event

When the alarms of an AlarmSet are displayed again with the "Unshelve" method, the event calls an instance of the "OnAlarmSetEventHandler" delegate.

Declares the event and the event handler for the new asynchronous displaying of the alarms.

```
event OnAlarmSetEventHandler OnUnshelveHandler
```

"OnAlarmSetEventHandler" delegate

Specifies the signature of the event handling method for all events of an AlarmSet.

```
void OnAlarmSetEventHandler(
     IAlarmSet sender,
     uint32 errorCode,
     IList<IAlarmSetResult> values,
     bool completed)
```

- `sender`
  Source of the event
- `errorCode`
  Error during asynchronous transfer

- `values`
  Event data as a list of "IAlarmSetResult" objects of the processed alarms.
- `completed`
  Status of the asynchronous transfer:
  - True: All alarms of the AlarmSet are processed.
  - False: Not all alarms of the AlarmSet are processed yet.

Example

Acknowledge active alarms from the "AlarmList" list as an AlarmSet asynchronously:

Copy code

```
public void AcknowledgeAlarms(IList<IAlarmResult> AlarmList)
{
    if (AlarmList != null)
    {
        if (AlarmList.Count == 1)
        {
            IAlarm alarmAck = runtime.GetObject<IAlarm>(AlarmList[0].Name);
            alarmAck.Acknowledge();
        }
        else
        {
            AlarmAckList = new List<IAlarmResult>();
            IAlarmSet alarmSet = runtime.GetObject<IAlarmSet>(); ;
            foreach (var alarmResult in AlarmList)
            {
                IAlarm pAlarm = null;
                pAlarm = alarmSet.Add(alarmResult.Name);
                AlarmAckList.Add(alarmResult);
            }

            // Assign callback function
            alarmSet.OnAcknowledgeHandler += alarmSet_OnAcknowledgeHandler;
            alarmSet.Acknowledge();
        }
    }
}

public void alarmSet_OnAcknowledgeHandler(IAlarmSet sender, uint errorCode,
IList<IAlarmSetResult> values, bool completed)
{
    foreach (var item in values)
    {
       System.Console.WriteLine(string.Format("InstanceId: {0} Name: {1} SystemName: {2} ",
item.InstanceId, item.Name, item.SystemName));
    }
}
```

Remove active alarms from the "AlarmList" list as an AlarmSet asynchronously:

Copy code

```
public void ResetAlarms(IList<IAlarmResult> AlarmList)
{
    if (AlarmList != null)
    {
        if (AlarmList.Count == 1)
        {
            IAlarm alarmReset = runtime.GetObject<IAlarm>(AlarmList[0].Name);
            alarmReset.Reset();
        }
        else
        {
            IAlarmSet alarmSet = runtime.GetObject<IAlarmSet>(); ;
            AlarmResetList = new List<IAlarmResult>();
            foreach (var alarmResult in AlarmList)
            {
                IAlarm pAlarm = null;
                pAlarm = alarmSet.Add(alarmResult.Name);
                AlarmResetList.Add(alarmResult);
            }
            alarmSet.OnResetHandler += alarmSet_OnReseteHandler;
            try
            {
                alarmSet.Reset();
            }
            catch (OdkException ex)
            {
                System.Console.WriteLine(string.Format("OdkException occurred {0}",
ex.Message));
            }
        }
    }
}

public void alarmSet_OnReseteHandler(IAlarmSet sender, uint errorCode,
IList<IAlarmSetResult> values, bool completed)
{
    try
    {
        foreach (var item in values)
        {
            System.Console.WriteLine(string.Format("InstanceId: {0} Name: {1} SystemName:
{2} ",
                item.InstanceId, item.Name, item.SystemName));
        }
    }
    finally
    {
        if (null != sender)
        {
            sender.Dispose();
        }
    }
}
```

IAlarmSetResult (Page 7887)

IAlarm (Page 7880)

IAlarmSetResult

Description

The C# interface "IAlarmSetResult" specifies properties of alarms in AlarmSets. These properties are returned by the EventHandler for all events of AlarmSets.

Members

The following properties are specified in the interface:

"SystemName" property

System name of the runtime system of an alarm in the AlarmSet

```
string SystemName { get; }
```

"Name" property

Name of an alarm in the AlarmSet

```
string Name { get; }
```

"InstanceId" property

InstanceID of an alarm in the AlarmSet

```
uint32 InstanceId { get; }
```

"Error" property

Error code of an alarm in the AlarmSet

```
uint32 Error { get; }
```

Example

Read out alarm of an AlarmSet after acknowledgment

Copy code

```
public void alarmSet_OnAcknowledgeHandler(IAlarmSet sender, uint errorCode,
IList<IAlarmSetResult> values, bool completed)
{
    try
    {
        foreach (var item in values)
        {
            System.Console.WriteLine(string.Format("InstanceId: {0} Name: {1} SystemName:
{2} ",
                item.InstanceId, item.Name, item.SystemName));
        }
    }
    finally
    {
        if (null != sender)
        {
            sender.Dispose();
        }
    }
}
```

IAlarmSet (Page 7882)

IAlarmTrigger

Description

The C# interface "IAlarmTrigger" specifies methods for triggering alarms.

Members

"CreateSystemAlarm" method

Creates an alarm of the SystemAlarmWithoutClearEvent class with the state machine alarm without "Inactive with acknowledgment" status.

```
void CreateSystemAlarm(object alarmText, string area, object
alarmParameterValue1, ...,  object alarmParameterValue7)
```

- `alarmText`:
  The alarm text. You have the following options:
  - Transfer a text list of the type "ITextList".
    The list entries of the text list can directly contain multilingual alarm texts or references to other text lists with multilingual alarm texts.

    Note

    Only user-defined text lists

    This method processes only user-defined text lists.

  - Transfer static string with monolingual text.
- `area`:
  The area of origin of the alarm
- `alarmParameterValue1` to `alarmParameterValue7`:
  User-defined comments

The alarm triggers an event with the following event path:

- For multilingual alarm texts:
  `@ScriptingSystemEvents.SystemAlarmWithoutClearEvent:SystemAlarmWithoutClearEvent`
- For monolingual alarm text:
  `@ScriptingSystemEvents.SystemAlarmWithoutClearEventText:SystemAlarmWithoutClearEvent`

"CreateSystemInformation" method

Creates an alarm of the SystemInformation class with the state machine alarm without "Inactive without acknowledgment" status.

```
void CreateSystemInformation(object alarmText, string area, object
alarmParameterValue1, ...,  object alarmParameterValue7)
```

- `alarmText`:
  The alarm text. You have the following options:
  - Transfer a text list of the type "ITextList".
    The list entries of the text list can directly contain multilingual alarm texts or references to other text lists with multilingual alarm texts.

    Note

    Only user-defined text lists

    This method processes only user-defined text lists.

  - Transfer static string with monolingual text.
- `area`:
  The area of origin of the alarm
- `alarmParameterValue1` to `alarmParameterValue7`:
  User-defined comments

The alarm triggers an event with the following event path:

- For multilingual alarm texts: `@ScriptingSystemEvents.SystemInformation:SystemInformation`
- For monolingual alarm text: `@ScriptingSystemEvents.SystemInformationText:SystemInformation`

"CreateOperatorInputInformation" method

Creates an alarm of the OperatorInputInformation class with the state machine alarm without "Inactive without acknowledgment" status.

```
void CreateOperatorInputInformation(object alarmText, string area,
object alarmParameterValue1, ...,  object alarmParameterValue7)
```

- `alarmText`:
  The alarm text. You have the following options:
  - Transfer a text list of the type "ITextList".
    The list entries of the text list can directly contain multilingual alarm texts or references to other text lists with multilingual alarm texts.

    Note

    Only user-defined text lists

    This method processes only user-defined text lists.

  - Transfer static string with monolingual text.
- `area`:
  The area of origin of the alarm
- `alarmParameterValue1` to `alarmParameterValue7`:
  User-defined comments

The alarm triggers an event with the following event path:

- For multilingual alarm texts:
  `@ScriptingSystemEvents.OperatorInputInformation:OperatorInputInformation`
- For monolingual alarm text:
  `@ScriptingSystemEvents.OperatorInputInformationText:OperatorInputInformation`

Example

The following code examples show how to trigger alarms of the class SystemAlarmWithoutClearEvent. Alarms of the classes SystemInformation and OperatorInputInformation are triggered in the same way.

Copying code

```
public void CreateSystemAlarm()
{
   //Create SystemAlarm with monolingual alarm text
    var alarm = runtime.GetObject<IAlarmSubscription>();
    var systemNames = new List<string>();
    systemNames.Add("SYSTEM1");
    alarm.OnAlarmHandler += alarm_OnAlarmHandler;
    alarm.OnPendingAlarmCompleteHandler += Alarm_OnPendingAlarmCompleteHandler;
    alarm.Filter = "AlarmClassName = 'SystemAlarmWithoutClearEvent'";
    alarm.Language = 1033;
    alarm.SystemNames = systemNames;
    alarm.Start();
    var systemAlarm = runtime.GetObject<IAlarmTrigger>();
    systemAlarm.CreateSystemAlarm(alarmText: "Alarm Text", area: "Area",
        alarmParameterValue1: "Param1",
        alarmParameterValue2: "Param2",
        alarmParameterValue3: "Param3",
        alarmParameterValue4: "Param4",
        alarmParameterValue5: "Param5",
        alarmParameterValue6: "Param6",
        alarmParameterValue7: "Param7");
    _event.WaitOne();
    _event.Reset();
    //stop alarm subscription
    alarm.Stop();
    //Dispose alarm object
    alarm.Dispose();
}

public void CreateSystemAlarmWithAlarmTextAsTextList()
{
   //Create SystemAlarm with multilingual alarm text; the tranlsations are directly stored
in the text list
    var alarm = runtime.GetObject<IAlarmSubscription>();
    var systemNames = new List<string>();
    systemNames.Add("SYSTEM1");
    alarm.OnAlarmHandler += alarm_OnAlarmHandler;
    alarm.OnPendingAlarmCompleteHandler += Alarm_OnPendingAlarmCompleteHandler;
    alarm.Filter = "AlarmClassName = 'SystemAlarmWithoutClearEvent'";
    alarm.Language = 1033;
    alarm.SystemNames = systemNames;
    alarm.Start();
    var systemAlarm = runtime.GetObject<IAlarmTrigger>();
     var texlistforAlarmText = runtime.GetObject<ITextList>();
    // Text list: AlarmTextTemplate
    // Test list entry index: 101
    // Text: "My input msg. input value = @1%d@"
    texlistforAlarmText.Name = "AlarmTextTemplate";
    texlistforAlarmText.TextListEntryIndex = 101;
    systemAlarm.CreateSystemAlarm(alarmText: texlistforAlarmText, area: "Area",
        alarmParameterValue1: "125", // dynamic value for format specifier @1%d@
        alarmParameterValue2: "Param2",
        alarmParameterValue3: "Param3",
        alarmParameterValue4: "Param4",
```

Copying code

```
        alarmParameterValue5: "Param5",
        alarmParameterValue6: "Param6",
        alarmParameterValue7: "Param7");
    _event.WaitOne();
    _event.Reset();
    //stop alarm subscription
    alarm.Stop();
    //Dispose alarm object
    alarm.Dispose();
}

public void CreateSystemAlarmWithTextListAsParameterValue()
{
   //Create SystemAlarm with multilingual alarm text; the text list references other text
lists with tranlsations
    var alarm = runtime.GetObject<IAlarmSubscription>();
    var systemNames = new List<string>();
    systemNames.Add("SYSTEM1");
    alarm.OnAlarmHandler += alarm_OnAlarmHandler;
    alarm.OnPendingAlarmCompleteHandler += Alarm_OnPendingAlarmCompleteHandler;
    alarm.Filter = "AlarmClassName = 'SystemAlarmWithoutClearEvent'";
    alarm.Language = 1033;
    alarm.SystemNames = systemNames;
    alarm.Start();
    var systemAlarm = runtime.GetObject<IAlarmTrigger>();
    var textList1 = runtime.GetObject<ITextList>("Text_List_1");
    var textList2 = runtime.GetObject<ITextList>("Text_List_2");
    textList1.TextListEntryIndex = 1; //Eng TL @1%t#2T@ Val: @3%s@
    systemAlarm.CreateSystemAlarm(alarmText: textList1, area: "Area",
    alarmParameterValue1: 1,
    alarmParameterValue2: textList2, // text list object
    alarmParameterValue3: "Hello"); // Dynamic value of @3%s@
    _event.WaitOne();
    _event.Reset();
    //stop alarm subscription
    alarm.Stop();
    //Dispose alarm object
    alarm.Dispose();
}
```

See also

ITextList (Page 7895)

ITextList

Description

The C# interface "ITextList" is used to transfer multilingual alarm texts for system alarms and operator input alarms. See section IAlarmTrigger (Page 7888), CreateSystemInformation method. An ITextList instance is passed to the alarm text. When the operator input alarm is generated, it is replaced by the configured text from the text list.

Members

"Name" property

The name of the text list.

```
string Name { get; set; }
```

"TextListEntryIndex" property

The index of the list entry

```
UInt32 TextListEntryIndex { get; set; }
```

IAlarmSubscription

Description

The C# interface "IAlarmSubscription" specifies methods for monitoring alarms of the runtime system.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Members

The following methods and events are specified in the interface:

"SystemNames" property

System names of runtime systems for the monitoring of active alarms

```
IList<string> SystemNames { get; set; }
```

"Language" property

Country identifier of the language of the monitored alarms

```
uint32 Language { get; set; }
```

"Filter" property

SQL-type string for filtering the result set of active alarms

```
string Filter { get; set; }
```

All properties of an alarm can be used in the filter string. The filter string can contain operators. Refer to the section Syntax of the alarm filter (Page 7828).

"Start" method

Subscribe systems for monitoring changes of active alarms.

```
void Start()
```

"Stop" method

Clear monitoring of active alarms.

Note

Start and Stop in Windows Forms applications

Do not call the "Stop" method for a Windows forms application in the same thread in which you called "Start".

```
void Stop()
```

"OnAlarmHandler" event

Following a change of the alarm state on subscribed systems, the event calls an instance of the "OnAlarmHandler" delegate.

Declares the event and the event handler for asynchronous monitoring of alarms.

```
event OnAlarmHandler OnAlarmHandler
```

"OnPendingAlarmCompleteHandler" event

After completion of the handling of all active alarms of a system, the event calls an instance of the "OnPendingAlarmCompleteHandler" delegate.

Declares the event and the event handler for confirmation of the asynchronous operations.

```
event OnPendingAlarmCompleteHandler OnPendingAlarmCompleteHandler
```

"OnAlarmHandler" delegate

Specifies the signature of the event handling method for the "OnAlarmHandler" event.

```
void OnAlarmHandler(
     IAlarmSubscription sender,
     uint32 systemError,
     string systemName,
     IList<IAlarmResult> values,
     bool completed)
```

- `sender`
  Reference to the "IAlarmSubscription" object
- `systemError`
  Error code for the asynchronous operation
- `systemName`
  Name of the runtime system that is subscribed for alarm monitoring by the user.

- `values`
  Event data as a list of "IAlarmResult" objects of the monitored active alarms.
- `completed`
  Status of the asynchronous transfer:
  - True: All alarms are read out.
  - False: Not all alarms are read out yet.

"OnPendingAlarmCompleteHandler" delegate

Specifies the signature of the event handling method for the "OnPendingAlarmCompleteHandler" event.

```
void OnPendingAlarmCompleteHandler(IAlarmSubscription sender)
```

- `sender`
  Source of the event

Example

Define functions for asynchronous monitoring of active alarms. Monitor "OnAlarmHandler" event and when occurring call the event handling method "alarm_OnAlarmHandler":

Copy code

```
public void SubscribeAlarmWithFilterOnOriginAndAlarmclass()
{
    try
    {
        //  object filter = "AlarmClass = 'AlarmWithOptionalAcknowledgement' AND Origin =
'Boiler'";
        IAlarmSubscription alarm = runtime.GetObject<IAlarmSubscription>();
        List<string> systemNames = new List<string>();
        systemNames.Add("SYSTEM1");

        // Assign alarm handler
        alarm.OnAlarmHandler += alarm_OnAlarmHandler;
        alarm.Filter = "AlarmClassName = 'AlarmWithOptionalAcknowledgement' AND Origin =
'Boiler'";
        alarm.Language = 1033;
        alarm.SystemNames = systemNames;
        alarm.Start();
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}

public void alarm_OnAlarmHandler(IAlarmSubscription sender, UInt32 nGlobalError, String
systemName, IList<IAlarmResult> value, bool completed)
{
    if (0 == nGlobalError)
    {
        try
        {
            AlarmList = new List<IAlarmResult>();
            foreach (var item in value)
            {
               System.Console.WriteLine(string.Format("InstanceID: {0} SourceID: {1} Name:
{2} State: {3} EventText: {4} StateText: {5} BackColor: {6} Flashing: {7} Quality: {8}
ModificationTime: {9}",
                    item.InstanceID, item.SourceID, item.Name, item.State,
                    item.EventText, item.StateText, item.BackColor, item.Flashing,
item.Quality, item.ModificationTime));
                AlarmList.Add(item);
            }

            // For test purpose: Cancel subscription after first notification
            AcknowledgeAlarms(AlarmList);
        }
        finally
        {
            if (null != sender)
            {
                sender.Stop();
                sender.Dispose();
            }
        }
    }
```

Copy code

```
    else
    {
        System.Console.WriteLine("AlarmSubscription Failed");
    }
}
```

See also

IAlarmResult (Page 7872)

IAlarm (Page 7880)

ILoggedAlarmResult

Description

The C# interface "ILoggedAlarmResult" specifies methods for accessing properties of logged alarms of a logging system.

Members

The following properties are specified in the interface:

"InstanceID" property

InstanceID for a logged alarm with multiple instances

```
uint32 InstanceID { get; }
```

"Name" property

Name of the logged alarm

```
string Name { get; }
```

"AlarmClassName" property

Name of the alarm class of the logged alarm

```
string AlarmClassName { get; }
```

"AlarmClassSymbol" property

Symbol of the alarm class of the logged alarm

```
string AlarmClassSymbol { get; }
```

"AlarmParameterValues" property

Parameter values of the logged alarm

```
IReadOnlyList<object> AlarmParameterValues { get; }
```

"AlarmText1" ... "AlarmText9" properties

Additional texts 1-9 of the logged alarm

```
string AlarmText1 { get; }
...
string AlarmText9 { get; }
```

"ChangeReason" property

Trigger event for modification of the alarm state of the logged alarm

```
uint16 ChangeReason { get; }
```

"Connection" property

Connection via which the logged alarm was triggered

```
string Connection { get; }
```

"State" property

Alarm state of the logged alarm

```
HmiAlarmState State { get; }
```

The enumeration "HmiAlarmState" can contain the following values:

- Standard (0x00)
- Raised (0x01)
- RaisedCleared (0x02)
- RaisedAcknowledged (0x05)
- RaisedAcknowledgedCleared (0x06)
- RaisedClearedAcknowledged (0x07)
- Removed (0x80)

"StateText" property

Alarm state of the logged alarm as text, for example, "active" or "inactive"

```
string StateText { get; }
```

"EventText" property

Text of the logged alarm that describes the alarm event

```
string EventText { get; }
```

"TextColor" property

Text color of the alarm state of the logged alarm

```
uint32 TextColor { get; }
```

"BackColor" property

Background color of the alarm state of the logged alarm

```
uint32 BackColor { get; }
```

"Flashing" property

Indicates whether a logged alarm is flashing.

```
bool Flashing { get; }
```

"InvalidFlags" property

Identification of the logged alarm with invalid data

```
byte InvalidFlags { get; }
```

"ModificationTime" property

Time of the last modification to the alarm state of the logged alarm

```
DateTime ModificationTime { get; }
```

"RaiseTime" property

Trigger time of the logged alarm

```
DateTime RaiseTime { get; }
```

"AcknowledgementTime" property

Time of alarm acknowledgment of the logged alarm

```
DateTime AcknowledgementTime { get; }
```

"ClearTime" property

Time of reset of the logged alarm

```
DateTime ClearTime { get; }
```

"ResetTime" property

Time of reset of the logged alarm

```
DateTime ResetTime { get; }
```

"SuppressionState" property

Status of visibility of the logged alarm

```
byte SuppressionState { get; }
```

"SystemSeverity" property

Severity of the system error

```
byte SystemSeverity { get; }
```

"Priority" property

Relevance for display and sorting of the logged alarm

```
byte Priority { get; }
```

"Origin" property

Origin for display and sorting of the logged alarm

```
string Origin { get; }
```

"Area" property

Origin area for display and sorting of the logged alarm

```
string Area { get; }
```

"Value" property

Process value of the logged alarm

```
object Value { get; }
```

"AlarmGroupName" property

Name of the group to which the alarm belongs. Blank if the alarm does not belong to a group.

```
string AlarmGroupName { get; }
```

"DeadBand" property

Range of the triggering tag in which no alarms are generated.

```
object DeadBand { get; }
```

"HostName" property

Name of the host that triggered the alarm.

```
string HostName { get; }
```

"InfoText" property

Localizable text for the alarm that contains the associated work instruction.

```
string InfoText { get; }
```

"StateMachine" property

StateMachine model of the alarm. The StateMachine represents the behavior of alarms through the arrangement of alarm states and alarm events, e.g. "RaiseClear", "RaiseRequiresAcknowledgment" or "RaiseClearOptionalAcknowledgment".

```
byte StateMachine { get; }
```

"ValueQuality" property

Quality of the process value of the alarm

```
int32 ValueQuality { get; }
```

"ValueLimit" property

Process value limit of the logged alarm

```
object ValueLimit { get; }
```

"SingleAcknowledgement" property

Indicates whether an alarm may be acknowledged only individually or may be acknowledged as a group or multiple selection.

```
bool SingleAcknowledgement { get; }
```

"LoggedAlarmStateObjectID" property

ID of alarm state for referencing within the logging system.

```
string LoggedAlarmStateObjectID { get; }
```

"ID" property

User-defined ID of the alarm that is also used in the display.

```
uint32 ID { get; }
```

"SourceType" property

Source from which the alarm was generated, for example, tag-based, controller-based or system-based alarm.

```
HmiAlarmSourceType SourceType { get; }
```

The enumeration "HmiAlarmSourceType" can contain the following values:

- `Undefined` (0)
- `Tag` (1)
- `Controller` (2)
- `System` (3)
- `Alarm` (4)

"UserName" property

User name of the logged operator input alarm

```
string UserName { get; }
```

"UserResponse" property

Expected or required user response to the logged alarm

```
byte UserResponse { get; }
```

"LoopInAlarm" property

Function that navigates from the alarm control to its origin.

```
string LoopInAlarm { get; }
```

"Error" property

Error code of the logged alarm

```
unit32 Error { get; }
```

"Duration" property

Returns the time interval in nanoseconds between triggering of the logged alarm and its previous status change.

```
TimeSpan  Duration { get; }
```

IAlarmLogging (Page 7905)

IAlarmLoggingSubscription (Page 7907)

IAlarmLogging

Description

The C# interface "IAlarmLogging" specifies properties and methods for reading out logged alarms of a logging system.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Members

The following methods and events are specified in the interface:

"Read" method

Read out logged alarms of a time period synchronously from logging system.

```
IList<ILoggedAlarmResult> Read(
     DateTime begin,
     DateTime end,
     string filter,
     uint32 language,
     IList<string> systemNames)
```

- `begin`
  Start date of the time period
- `end`
  End date of the time period
- `filter`
  Filter for limiting the read operation with properties of the "ILoggedAlarmResult" object.
- `language`
  Country identification of the language of the logged alarm text
- `systemNames`
  System names of the runtime systems of the logged alarms. Default: local system

"ReadAsync" method

Read out logged alarms of a time period asynchronously from logging system.

```
void ReadAsync(
     DateTime begin,
     DateTime end,
     string filter,
```

```
    uint32 language,
    IList<string> systemNames)
```

- `begin`
  Start date of the time period
- `end`
  End date of the time period
- `filter`
  Filter for limiting the read operation with properties of the "ILoggedAlarmResult" object.
- `language`
  Country identification of the language of the logged alarm text
- `systemNames`
  System names of the runtime systems of the logged alarms. Default: local system

"OnReadComplete" event

After readout of the logged alarms, the event calls an instance of the "OnReadCompleteAlarmLoggingHandler" delegate.

Declares the event and the event handler for the asynchronous readout of logged alarms.

```
event OnReadCompleteAlarmLoggingHandler OnReadComplete
```

"OnReadCompleteAlarmLoggingHandler" delegate

Specifies the signature of the event handling method for the "OnReadComplete" event.

```
void OnReadCompleteAlarmLoggingHandler(
     IAlarmLogging sender,
     uint32 errorCode,
     IList<ILoggedAlarmResult> values,
     bool completed)
```

- `sender`
  Source of the event
- `errorCode`
  Error code for the asynchronous operation
- `values`
  Event data as a list of "ILoggedAlarmResult" objects of the read-out logged alarms.
- `completed`
  Status of the asynchronous transfer:
  - True: All alarms are read out.
  - False: Not all alarms are read out yet.

Example

Reading out and outputting logged alarms asynchronously:

Copy code

```
public void ReadAsync()
{
    try
    {
        var alarm = _runtime.GetObject<IAlarmLogging>();
        var now = DateTime.UtcNow;
        var begin = now.AddMinutes(-5);
        var end = now.AddMinutes(-2);
        List<string> systemNames = new List<string>();
        systemNames.Add("SYSTEM1");
        alarm.OnReadComplete += Alarm_OnReadComplete;
        alarm.ReadAsync(begin, end, "", 1033, systemNames);
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}

private void Alarm_OnReadComplete(IAlarmLogging sender, uint errorCode,
IList<ILoggedAlarmResult> values, bool completed)
{
    PrintValues(values);
    sender.Dispose();
}

private void PrintValues(IList<ILoggedAlarmResult> values)
{
    foreach (var v in values)
    {
        Console.WriteLine(string.Format("Name: {0} Timestamp: {1} Value: {2}", v.Name,
v.RaiseTime, v.Value));
    }
}
```

ILoggedAlarmResult (Page 7900)

IAlarmLoggingSubscription (Page 7907)

IAlarmLoggingSubscription

Description

The C# interface "IAlarmLoggingSubscription" specifies properties and methods for monitoring logged alarms of a logging system.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Members

The following properties, methods and events are specified in the interface:

"SystemNames" property

System names of the runtime systems of the logged alarms

```
IList<string> SystemNames { get; set; }
```

"Language" property

Country identification of the language of the logged alarms

```
uint32 Language { get; set; }
```

"Filter" property

SQL-type string for filtering the result set of the logged alarms

```
string Filter { get; set; }
```

"Start" method

Start monitoring of logged alarms.

```
void Start()
```

"Stop" method

Stop monitoring of all logged alarms.

```
void Stop()
```

"OnDataChanged" event

Following a change of a monitored alarm in the logging systems, the event calls an instance of the "OnDataChangedAlarmLoggingHandler" delegate.

Declares the event and the event handler for the monitoring of logged alarms.

```
event OnDataChangedAlarmLoggingHandler OnDataChanged
```

"OnDataChangedAlarmLoggingHandler" delegate

Specifies the signature of the event handling method for the "OnDataChanged" event.

```
void OnDataChangedAlarmLoggingHandler(
     IAlarmLoggingSubscription sender,
```

```
    uint32 errorCode,
    IList<ILoggedAlarmResult> values)
```

- `sender`
  Source of the event
- `errorCode`
  Error code for the asynchronous operation
- `values`
  Event data as a list of "ILoggedAlarmResult" objects of the monitored logged alarms.

Example

Output logged alarms following a change:

Copy code

```
public void SubscribeAlarm()
{
    try
    {
        _alarm = _runtime.GetObject<IAlarmLoggingSubscription>();
        List<string> systemNames = new List<string>();
        systemNames.Add("SYSTEM1");
        // Assign alarm handler
        _alarm.OnDataChanged += Alarm_OnDataChanged;
        _alarm.Filter = "";
        _alarm.Language = 1033;
        _alarm.SystemNames = systemNames;
        _alarm.Start();
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}

private void Alarm_OnDataChanged(IAlarmLoggingSubscription sender, uint errorCode,
IList<ILoggedAlarmResult> values)
{
    PrintValues(values);
}

private void PrintValues(IList<ILoggedAlarmResult> values)
{
    foreach (var v in values)
    {
        Console.WriteLine(string.Format("Name: {0} Timestamp: {1} Value: {2}", v.Name,
v.RaiseTime, v.Value));
    }
}
```

Cancel monitoring of logged alarms:

Copy code

```
public void CancelSubscription()
{
    try
    {
        if (_alarm != null)
        {
            _alarm.Stop();
            _alarm.Dispose();
        }
    }
    catch(Exception ex)
    {
        System.Console.WriteLine(ex.Message);
    }
}
```

IAlarmLogging (Page 7905)

ILoggedAlarmResult (Page 7900)

20.3.8.6 Interfaces for connections

IConnectionResult

Description

The C# interface "IConnectionResult" provides access to the details of a connection.

Members

The following properties are specified in the interface:

"Name" property

Name of the connection

```
string Name { get; }
```

"ConnectionState" property

Status of the connection

```
HmiConnectionState ConnectionState { get; }
```

The "HmiConnectionState" enumeration contains the following values:

- `Disabled` (0)
- `Connecting` (1)

- `Connected` (2)
- `Disconnecting` (3)
- `Disconnected` (4)
- `Reconnecting` (5)

"EstablishmentMode" property

Mode in which the connection will be established.

```
HmiConnectionEstablishmentMode EstablishmentMode { get; }
```

The "HmiConnectionEstablishmentMode" enumeration contains the following values:

- `None` (0)
- `AutomaticActive` (1)
- `AutomaticPassive` (2)
- `OnDemandActive` (3)
- `OnDemandPassive` (4)

"TimeSynchronizationMode" property

Mode of time synchronization between HMI system and automation system

```
HmiTimeSynchronizationMode TimeSynchronizationMode { get; }
```

The "HmiTimeSynchronizationMode" enumeration contains the following values:

- `None` (0)
- `Subordinate` (1)
- `Lead` (2)

"DisabledAtStartup" property

Indicates whether the connection is disabled at the start of Runtime.

```
bool DisabledAtStartup { get; }
```

- `true`: Connection is disabled at the connection start.
- `false`: Connection is active at the connection start.

"Enabled" property

Indicates whether the connection is active.

```
bool Enabled { get; }
```

- `true`: Connection is active.
- `false`: Connection is not active.

"ConnectionType" property

Protocol of a communication driver, e.g. "S7 Classic".

```
string ConnectionType { get; }
```

"Error" property

Error code of the connection

```
uint32 Error { get; }
```

Example

Output connection details:

Copy code

```
public void Connection_Read()
{
    var (connection = m_runtime.GetObject<IConnection>("HMI-ConnectionS7Plus");
    if (connection != null)
    {
        var con = connection.Read();
        if (con != null)
        {
            Console.WriteLine("Connection Name is  {0} ", con.Name);
            Console.WriteLine("ConnectionState is  {0}", con.ConnectionState);
           Console.WriteLine("TimeSynchronizationMode is {0} ", con.TimeSynchronizationMod
e);
            Console.WriteLine("EstablishMentMode is  {0} ", con.EstablishmentMode);
            Console.WriteLine("Enabled is  {0} ", con.Enabled);
            Console.WriteLine("DisabledAtStartup is  {0} ", con.DisabledAtStartup);
            Console.WriteLine("ConnectionType is  {0} ", con.ConnectionType);
            Console.WriteLine(" Error is {0} ", con.Error);
        }
    }
}
```

See also

IConnection (Page 7913)

IConnectionSet (Page 7915)

IConnectionStatusResult

Description

The C# interface "IConnectionStatusResult" provides access to the status of a connection.

Members

The following properties are specified in the interface:

"Name" property

Name of the connection

```
string Name { get; }
```

"ConnectionState" property

Status of the connection

```
HmiConnectionState ConnectionState { get; }
```

The "HmiConnectionState" enumeration contains the following values:

- `Disabled` (0)
- `Connecting` (1)
- `Connected` (2)
- `Disconnecting` (3)
- `Disconnected` (4)
- `Reconnecting` (5)

"Error" property

Error code of the connection

```
uint32 Error { get; }
```

Example

Output status of a certain connection:

Copy code

```
public void Connection_GetConnectionState()
{
    var connection = m_runtime.GetObject<IConnection>("HMI-ConnectionS7Plus");
    var con = connection.GetConnectionState();
    if (con != null)
    {
        Console.WriteLine("Connection Name is : {0} ", con.Name);
        Console.WriteLine(" Error is : {0} ", con.Error);
        Console.WriteLine("Connection status is: {0}", con.ConnectionStatus);
    }
}
```

See also

IConnection (Page 7913)

IConnectionSet (Page 7915)

IConnection

Description

The C# interface "IConnection" provides properties and methods for the access to a connection. A connection is a configured, logical assignment of two communication partners.

The interface inherits the `Dispose` method of the "IDisposable" interface of the .NET framework.

Members

The following properties and methods are specified in the interface:

"Name" property

Name of the connection

```
string Name { get; set; }
```

"Read" method

Read connection details synchronously from the Runtime system.

```
IConnectionResult Read()
```

"GetConnectionState" method

Return connection status of a connection.

```
IConnectionStatusResult GetConnectionState()
```

"SetConnectionMode" method

Change connection status of a connection.

```
void SetConnectionMode(ConnectionMode mode)
```

The "ConnectionMode" enumeration contains the following values:

- `Disabled` (0)
- `Enabled` (1)

Examples

Disable connection:

Copy code

```
public void Connection_SetConnectionStateDisable()
{
    var connection = m_runtime.GetObject<IConnection>("HMI-ConnectionS7Plus");
    if (connection != null)
    {
        connection.SetConnectionMode(ConnectionMode.Disabled);
    }
}
```

Enable connection:

Copy code

```
public void SetConnectionStateEnable()
{
    using (IConnection connection = runtime.GetObject<IConnection>("HMI-ConnectionS7Plus"))
    {
        if (connection != null)
        {
            connection.SetConnectionMode(ConnectionMode.Enabled);
        }
    }
}
```

See also

IConnectionSet (Page 7915)

IConnectionResult (Page 7910)

IConnectionStatusResult (Page 7912)

IConnectionSet

Description

The C# interface "IConnectionSet" specifies properties, methods and events for optimized access to several connections of the Runtime system.

After initialization of the "IConnectionSet" object, you have read/write access to multiple connections in one call. Simultaneous access takes place with better performance and lower communication load than single access to multiple connections.

The interface inherits the `Dispose` method of the "IDisposable" interface of the .NET framework.

Members

The following properties, methods and events are specified in the interface:

"ContextId" property

ID as additional identification feature of a connection. The ContextId can, for example, be used to recognize identically named connections.

Default value -1: The ContextId is not used.

```
int32 ContextId { get; set; }
```

Access operator "this[string]"

Accessing or changing an element of a ConnectionSet via the connection name.

```
IConnection this[string connectionName] { get; set; }
```

`connectionName`
Name of the connection

"Count" property

Number of connections of a connection set list

```
int32 Cont { get; }
```

"Add" method

Add connections to a connection set.

```
void Add(ICollection<string> connections)
```

`connections`
List of connections for the connection set

"Remove" method

Remove individual connection from connection set.

```
void Remove(string connection)
```

`connection`
Name of connection that is removed from the connection set.

"Clear" method

Remove all connections from connection set.

```
void Clear()
```

"Read" method

Read connection details of all connections of the connection set synchronously from the Runtime system.

```
IList<IConnectionResult> Read()
```

"ReadAsync" method

Read connection details of all connections of the connection set asynchronously from the Runtime system.

```
void ReadAsync()
```

"GetConnectionState" method

Read connection status of all connections of the connection set synchronously from the Runtime system.

```
IList<IConnectionStatusResult> GetConnectionState()
```

"Subscribe" method

Subscribe all connections of a connection set asynchronously for change monitoring.

```
void Subscribe()
```

"CancelSubscribe" method

Cancel change monitoring of all connections of a connection set.

```
void CancelSubscribe()
```

"OnConnectionRead" event

After establishment of the connection, event calls an instance of the "OnConnectionHandler" delegate.

Declares the event and the event handler for the establishment of a connection.

```
event OnConnectionHandler OnConnectionRead
```

"OnConnectionStateChange" event

After change of the connection status, event calls an instance of the "OnConnectionStateChangeHandler" delegate.

Declares the event and the event handler for the change of the connection status.

```
event OnConnectionStateChangeHandler OnConnectionStateChange
```

"OnConnectionHandler" delegate

Specifies the signature of the event handling method for the "OnConnectionHandler" event of a connection set.

```
void OnConnectionHandler(
     IConnectionSet sender,
     uint32 systemError,
     IList<IConnectionResult> values)
```

- `sender`
  Source of the event
- `systemError`
  Error code
- `values`
  List of connections

"OnConnectionStateChangeHandler" delegate

Specifies the signature of the event handling method for the "OnConnectionStateChangeHandler" event of a connection set.

```
void OnConnectionStateChangeHandler(
    IConnectionSet  sender,
    uint32 systemError,
    IList<IConnectionStatusResult> values)
```

- `sender`
  Source of the event
- `systemError`
  Error code
- `values`
  List of status changes of the connections

Examples

Monitor connection status:

Copy code

```
public void ConnnectionSet_Subscribe()
{
    Console.WriteLine(" ......Connection Set:Subscription start ......");
    using (IConnectionSet subscribe = runtime.GetObject<IConnectionSet>())
    {
        if (subscribe != null)
        {
            ICollection<string> list = new string[] { "HMI-Connection", "HMI-
ConnectionS7Plus" };
            subscribe.Add(list);
            subscribe.OnConnectionStateChanged += Subscribe_OnConnectionStateChanged;
            subscribe.Subscribe();
            Thread.Sleep(500);
        }
    }
}

private void Subscribe_OnConnectionStateChanged(IConnectionSet sender, uint systemError,
IList<IConnectionStatusResult> values)
{
    if (0 == systemError)
    {
        try
        {
            foreach (var item in values)
            {
                Console.WriteLine("Name:{0} ", item.Name);
                Console.WriteLine("State:{0} ", item.ConnectionStatus.ToString());
                Console.WriteLine("Error:{0} ", item.Error);
            }
        }

        catch (OdkException ex)
        {
        System.Console.WriteLine(string.Format("OdkException occured {0}", ex.Message));
        }

        finally
        {
            if (null != sender)
            {
                sender.CancelSubscribe();
                Console.WriteLine("Subscription cancelled");
                sender.Dispose();
            }
        }
    }
    else
    {
        System.Console.WriteLine("Connection set subscription  Failed");
    }
}
```

Copy code

Read out connection synchronously:

Copy code

```
public void ConnectionSet_Read()
{
    Console.WriteLine(" .......Connection Set: Read ...... ");
    using (IConnectionSet read = runtime.GetObject<IConnectionSet>())
    {
        if (read != null)
        {
            ICollection<string> list = new string[] { "HMI-Connection", "HMI-
ConnectionS7Plus" };
            read.Add(list);

            IList<IConnectionResult> connectionResult = read.Read();
            foreach (var item in connectionResult)
            {
                System.Console.WriteLine(string.Format("Connection Name is  {0} ",
item.Name));
                System.Console.WriteLine(string.Format("ConnectionState is  {0}",
item.ConnectionState.ToString()));
                System.Console.WriteLine(string.Format("TimeSynchronizationMode is {0} ",
item.TimeSynchronizationMode.ToString()));
                System.Console.WriteLine(string.Format(" Error is {0} ", item.Error));
                System.Console.WriteLine(string.Format("EstablishMentMode is  {0} ",
item.EstablishmentMode));
                System.Console.WriteLine(string.Format("Enabled is  {0} ", item.Enabled));
                System.Console.WriteLine(string.Format("DisabledAtStartup is  {0} ",
item.DisabledAtStartup));
                System.Console.WriteLine(string.Format("ConnectionType is  {0} ",
item.ConnectionType));
            }
        }
    }
}
```

Read out connection asynchronously:

Copy code

```
public void ConnectionSet_ReadAsync()
{
    Console.WriteLine(" ......Connection Set: ReadAsync start ......");
    IConnectionSet readAsync = runtime.GetObject<IConnectionSet>();
    if (readAsync != null)
    {
       ICollection<string> list = new string[] { "HMI-Connection", "HMI-ConnectionS7Plus" };
        readAsync.Add(list);
        readAsync.OnConnectionRead += Read_OnConnectionComplete;
        readAsync.ReadAsync();
        Thread.Sleep(5000);
    }
}

private void Read_OnConnectionComplete(IConnectionSet sender, uint systemError,
IList<IConnectionResult> values)
{
    foreach (var item in values)
    {
        Console.WriteLine("Name:{0} ", item.Name);
        Console.WriteLine("State:{0} ", item.ConnectionState);
        Console.WriteLine("establishmentMode:{0} ", item.EstablishmentMode);
        Console.WriteLine("TimeSynchronizationMode:{0} ", item.TimeSynchronizationMode);
        Console.WriteLine("ConnectionType:{0} ", item.ConnectionType);
        Console.WriteLine("Enabled:{0} ", item.Enabled);
        Console.WriteLine("DisabledAtStartup:{0} ", item.DisabledAtStartup);
        Console.WriteLine("Error:{0} ", item.Error);
    }
}
    finally
    {
        if (null != sender)
        {
            sender.Dispose();
        }
    }
}
```

IConnectionStatusResult (Page 7912)

20.3.8.7 Interfaces of the Plant Model

IPlantModel

Description

The C# interface "IPlantModel" specifies methods for access to object instances of the plant model of a Runtime system. The "IPlantModel" object represents the plant model of the graphical Runtime system.

The interface inherits the `Dispose` method of the "IDisposable" interface of the .NET framework.

Formatting a path in the hierarchy

A hierarchy path of object instances consists of several components and has the following syntax:

```
[SystemName].HierarchyName::[PlantObjectID/.../]PlantObjectID
```

The system name can be omitted for referencing a local hierarchy. The dot before the hierarchy name must stay.

Note

Fixed code HierarchyName

In the current version, `HierarchyName` has a fixed code which is "hierarchy".

Members

The class implements the following methods:

"GetPlantObject" method

Supplies an object instance of "IPlantObject".

```
IPlantObject GetPlantObject(string  plantObject)
```

- `plantObject`
  Identifies an `IPlantObject` instance by its name or its path in the hierarchy.

"GetPlantObjectsByType" method

Supplies a list with instances of "IPlantObject" that have a specific type.

```
IList<IPlantObject> GetPlantObjectsByType(string
plantObjectTypeFilter, string viewFilter = null)
```

- `plantObjectTypeFilter`
  Filter for the "IPlantObject" type on which the instances are based.
- Optional: `viewFilter`
  Filter for the path in the hierarchy. Only instances from a specific node are returned.

"GetPlantObjectsByExpression" method

Supplies a list with instances of "IPlantObject" instances. The instances are filtered by type and property values.

```
IList<IPlantObject> GetPlantObjectsByExpression(ICollection<string>
propertyNames, string plantObjectTypeFilter, string
expressionFilter, string viewFilter)
```

- `propertyNames`
  A list with property names
- `plantObjectTypeFilter`
  Filter for the object type on which the instances are based.
- `expressionFilter`
  An expression that is a filter for the property values.
- Optional: `viewFilter`
  Filter for a hierarchy path.

Example:

```
var plantObjectArr =
PlantModel.GetPlantObjectsByExpression("Temperature", "Motor",
"Temperature>100");
```

"GetPlantObjectsByPropertyNames" method

Supplies a list with "IPlantObject" instances that have specific properties and originate in a specific plant node.

```
IList<IPlantObject>
GetPlantObjectsByPropertyNames(ICollection<string> propertyNames,
string viewFilter = null)
```

- `propertyNames`
  A list with property names
  If the list contains multiple values, all properties must be available at the object.
- Optional: `viewFilter`
  Filter for a hierarchy path.

Example

Example of a hierarchy path:

Hierarchy path	Referenced object instance
`System2.TechnologicalHierarchy::P1/S1/L2/LeftPump`	References the "LeftPump" object instance in the "TechnologicalHierarchiy" of system2.
`.TechnologicalHierarchy::P1/S1/L2/LeftPump`	References the "LeftPump" object instance in the "TechnologicalHierarchiy" of the local system.
`U4711`	References the "U4711" object instance of the local system.
`System2::U4711`	References the "U4711" object instance of System2.

Sample code

Copy code

```
public void Odk_GetPlantObjectsByType()
{
    using (IPlantModel myPlantModel = runtime.GetObject<IPlantModel>())
    {    //gets node for specified Node path
        IList<IPlantObject> plantObject =
myPlantModel.GetPlantObjectsByType("RUNTIME_1::NodeType1",
        ".hierarchy::RootNodeName\\Node1");

        if (plantObject.Count() > 0)
        {
             foreach (IPlantObject item in plantObject)
             {
                 System.Console.WriteLine(string.Format("ViewName: {0} Name: {1}",
item.CurrentPlantView, item.Name));
             }
        }
    }
}
```

IPlantObject

Description

The C# interface "IPlantObject" specifies properties and methods for handling object instances of the plant model of a Runtime system.

An object instance in the plant model is based on an object type and its data structure. Each object instance receives its position within the hierarchy by assigning it to a hierarchy node.

The interface inherits the `Dispose` method of the "IDisposable" interface of the .NET framework.

Formatting of a hierarchy path

A hierarchy path of object instances consists of several components and has the following syntax:

`[SystemName].HierarchyName::[PlantObjectID/.../]PlantObjectID`

The system name can be omitted for referencing a local hierarchy. The dot before the hierarchy name must stay.

Members

The following properties, methods and events are specified in the interface:

"Name" property

The name for unique identification of the object instance.

```
string Name { get; }
```

"Parent" property

The parent object instance in the hierarchy.

```
IPlantObject Parent { get; }
```

"Children" property

List of child object instances in the hierarchy

```
IReadOnlyList<IPlantObject> Children { get; }
```

"PlantViewPaths" property

The dictionary with string/string pairs that maps the hierarchy names to the hierarchy paths for all hierarchies that contain the "IPlantObject" instance (hierarchy name to hierarchy path).

```
IReadOnlyDictionary<string, string> PlantViewPaths { get; }
```

"CurrentPlantView" property

Path and name of the object instance in the currently selected hierarchy, e.g. "Maintenance".

The "CurrentPlantView" property is used as basis for navigation with the "Parent" or "Children" properties. If the object instance is only contained in one hierarchy, "CurrentPlantView" contains its path. If the object is contained in several views, the hierarchy path must be set via this property before the "Parent" or "Children" property can be used.

```
string CurrentPlantView { get; set; }
```

"GetProperty" method

Supplies a property of the object instance.

```
IPlantObjectProperty GetProperty(string propertyName)
```

`propertyName`
Name of an object instance property

"GetProperties" method

Supplies a two-dimensional list (name-object pairs) of the data structure of the object instance. The list allows access to the instance properties.

```
IPlantObjectPropertySet GetProperties(ICollection<string>
propertyNames = null)
```

- Optional: `propertyNames`
  List with names of one or multiple object instance properties.
  Without parameters, all properties of an object instance are returned

"GetActiveAlarms" method

Supplies all active alarms that the object instance contains at the time it is called in the active hierarchy. Unlike with an AlarmSubscription, no status changes or new alarms are signaled that occur after the function call. Users can filter the alarms or specify a SystemName if they only want to receive the active alarms of a specific system.

```
void GetActiveAlarms(UInt32 languageId, bool includeChildren =
false, string filter = null);
```

- `languageID`
  Language code of the language for all texts of an alarm and the filters. Refer to the section Locale IDs of the supported languages (Page 7829).
- Optional: `includeChildren`
  The active alarms of the child instances are returned as well.
- Optional: `filter`
  SQL-type string for filtering the alarm texts. The filter can contain operators. See also Syntax of the alarm filter (Page 7828).

"CreateAlarmSubscription" method

Supplies a "PlantObjectAlarmSubscription" that can be used to start and stop an alarm subscription.

```
IPlantObjectAlarmSubscription CreateAlarmSubscription();
```

"PlantObjectAlarmHandler" event

The event calls an instance of the "OnPlantObjectAlarmHandler" delegate.

```
event OnPlantObjectAlarmHandler PlantObjectAlarmHandler;
```

"OnPlantObjectAlarmHandler" delegate

Specifies the signature of the event handling method for the "`PlantObjectAlarmHandler`" event of an "IPlantObject" instance.

```
public delegate void OnPlantObjectAlarmHandler(
        IPlantObject sender,
        UInt32 systemError,
        string systemName,
        IList<IAlarmResult> values,
        bool completed);
```

- `sender`
  Source of the event
- `systemError`
  Supplies an error code when a global error has occurred. When the error code is set, `values` is irrelevant.
- `systemName`
  Name of the runtime system that is subscribed for alarm monitoring by the user.
- `values`
  Event data as a list of "IAlarmResult" instances of the monitored active alarm.
- `completed`
  Status of the asynchronous transfer:
  - `True`: All alarms are read out.
  - `False`: Not all alarms are read out yet.

Example

Copy code

```
public void Odk_PlantObjectGetProperties()
{
   var myPlantModel = _runtime.GetObject<IPlantModel>();
   var strNodeName = ".hierarchy::RootNodeName/Node1";
   var plantObject = myPlantModel.GetPlantObject(strNodeName);
   Console.WriteLine("ViewName: {0} Name: {1}", plantObject.CurrentPlantView, plantObject.Name);
   // get the  plant objectproperties by propeyty names
   var plantObjectProperties = plantObject.GetProperties();
   if (plantObjectProperties != null)
   {
      var nCount = plantObjectProperties.Count;
      var listPropValues = plantObjectProperties.Read();
      Console.WriteLine("Number of Properties {0}", nCount);
      foreach (var item in listPropValues)
      {
         Console.WriteLine("Property Name is {0}  ", item.Name);
         Console.WriteLine("Property Value is {0}  ", item.Value);
         Console.WriteLine("Property Quality is {0} ", item.Quality);
         Console.WriteLine("Property Error is {0} ", item.Error);
      }
   }
}
```

IPlantObjectProperty

Description

The C# interface "IPlantObjectProperty" specifies the handling of properties of object instances of the plant model of a Runtime system. The properties represent the data structure of an object instance.

The object instance communicates with the automation system through the properties of the data structure. The values of the properties are obtained from linked process tags or internal tags.

You reference an "IPlantObjectProperty" object using the `IPlantObject.GetProperty` or `IPlantObject.GetProperties` method.

The interface inherits the `Dispose` method of the "IDisposable" interface of the .NET framework.

Members

The interface has the following properties and methods:

"Name" property

Name of the property

```
string Name { get; }
```

"Read" method

Reads the value of the "IPlantObjectProperty" instance synchronously and returns it as an "IPlantObjectPropertyValue" object. The value, the quality code and the time stamp of the property are determined when the property is read.

```
IPlantObjectPropertyValue Read()
```

"Write" method

Writes the value synchronously to the "IPlantObjectProperty" instance.

```
void Write(object Value)
```

- `Value`
  New process value of the property

Example

Copy code

```
public void Odk_PlantObjectGetPropertyWrite()
{
    using (IPlantModel myPlantModel = runtime.GetObject<IPlantModel>())
    {
       string strNodeName = ".hierarchy::RootNodeName\\Node1";    //gets node for specified
Node path
        using (IPlantObject plantobject = myPlantModel.GetPlantObject(strNodeName))
        {
            System.Console.WriteLine(string.Format("ViewName: {0} Name: {1}",
plantobject.CurrentPlantView, plantobject.Name));
            if (plantobject != null)
                {
                    string strName = "NodeProperty_1";
                    using (IPlantObjectProperty plantObjectProperty =
plantobject.GetProperty(strName))
                    {
                        if (plantObjectProperty != null)
                        {
                            IPlantObjectPropertyValue pValue = plantObjectProperty.Read();
                            System.Console.WriteLine(string.Format("Property Name: {0}
property value before write
                            operation: {1}", strName, pValue.Value));
                            Object value = 400; // Write Cpm Node Property
                            plantObjectProperty.Write(value);
                           IPlantObjectPropertyValue pValues = plantObjectProperty.Read();
                            System.Console.WriteLine(string.Format("Property Name: {0}
property value after write Operration: {1}",strName, pValues.Value));
                        }
                    }
                }
            }
        }
    }
}
```

IPlantObjectPropertyValue

Description

The C# interface "IPlantObjectPropertyValue" specifies the properties of process tags that are connected to an object instance property of the Runtime system.

Members

The following properties are specified in the interface:

"Name" property

Name of the tag

```
string Name { get; }
```

"Value" property

Value of the tag at the moment of the read operation.

```
object Value { get; }
```

"Quality" property

Quality code of the read operation of the tag.

```
Int32 Quality { get; }
```

"TimeStamp" property

Time stamp of the last successful read operation of the tag.

```
DateTime TimeStamp { get; }
```

"Error" method

Error code of the last read or write operation of the tag.

```
UInt32 Error { get; }
```

"OnPlantModelPropertySubscriptionHandler" delegate

Specifies the signature of the event handling method for the "`OnPlantModelPropertySubscriptionHandler`" event of an "IPlantObjectPropertySet" instance.

```
public delegate void OnPlantModelPropertySubscriptionHandler(
        IPlantObjectPropertySet sender,
         IList<IPlantObjectPropertyValue> values);
```

- `sender`
  Source of the event
- `values`
  Event data as a list of "IPlantObjectPropertyValue" instances of the monitored active alarm.

Example

Copy code

```
public void Odk_PlantObjectGetPropertyRead()
{
    using (var myPlantModel = _runtime.GetObject<IPlantModel>())
    {
        var strNodeName = ".hierarchy::RootNodeName/Node1";
        //gets node for specified Node path
        using (var plantobject = myPlantModel.GetPlantObject(strNodeName))
        {
            Console.WriteLine("ViewName: {0} Name: {1}", plantobject.CurrentPlantView, plantobject.Name);
            var strName = "NodeProperty_1";
            using (var plantObjectProperty = plantobject.GetProperty(strName))
            {
                if (plantObjectProperty != null)
                {
                    // Read Cpm Node Property
                    var plantObjectPropertyValue = plantObjectProperty.Read();
                    if (null != plantObjectPropertyValue)
                    {
                        Console.WriteLine(
                        "Name= {0} TimeStamp {1} QualityCode {2} Error {3} Value {4}",
                        plantObjectPropertyValue.Name, plantObjectPropertyValue.TimeStamp,
                        plantObjectPropertyValue.Quality, plantObjectPropertyValue.Error,
                        plantObjectPropertyValue.Value);
                    }
                }
            }
        }
    }
}
```

IPlantObjectPropertySet

Description

The C# interface "IPlantObjectPropertySet" specifies properties, methods and events for optimized access to several IPlantObjectProperty instances of the Runtime system.

After initialization of the "IPlantObjectPropertySet" object, you have read/write access to multiple IPlantObjectProperty instances in one call. Simultaneous access has better performance and a lower communication load than single access to multiple properties.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Member

The following properties, methods and events are specified in the interface:

"ContextID" property

"ContextID" can be useful for asynchronous methods. Users can assign "ContextID" if they have to assign the answer from the system to a read/write job.

Default value -1: "ContextId" is not used.

```
Int32 ContextId { get; set; }
```

"[propertyName]" property

Change the process value of a property of the "IPlantObjectPropertySet" instance.
The value is changed by the property only in the local "IPlantObjectPropertySet" instance. To write the values in the process image, a "Write" or "WriteAsync" method must be called.

```
object this[string propertyName] { get; set; }
```

- `propertyName`
  Name of the property that is changed in the PropertySet.

"Count" property

The number of properties of the "IPlantObjectPropertySet" instance.

```
Uint32 Count { get; }
```

"Read" method

Supplies a list with all values of the "IPlantObjectProperty" instances contained in the "IPlantObjectPropertySet" instance. The values are read synchronously.

```
IList<IPlantObjectPropertyValue> Read();
```

"ReadAsync" method

Reads the values of all "IPlantObjectProperty" instances of the "IPlantObjectPropertySet" instance asynchronously.

```
void ReadAsync()
```

"Write" method

Writes the values of the "IPlantProperty" instances of the "PlantObjectPropertySet" instance synchronously to the Runtime system. Write operation errors are returned in a list with "IErrorResult" instances.

```
IList<IErrorResult> Write()
```

"WriteAsync" method

Writes the values of all "IPlantObjectProperty" instances of the "PlantObjectPropertySet" instance asynchronously to the Runtime system.

```
void WriteAsync()
```

"Subscribe" method

Subscribes all properties of the "IPlantObjectPropertySet" instance asynchronously for change monitoring.

```
void Subscribe()
```

"Add" method

Adds one or more "IPlantObjectProperty" instances to the "IPlantObjectPropertySet" instance.

The method can be called as follows:

- Adding multiple "IPlantObjectProperty" instances without value:
  `void Add(ICollection<string> propertyNames)`
  - `name`
    A collection with the names of the "IPlantObjectProperty" instances.
- Adding a "IPlantObjectProperty" instance with value:
  `void Add(string propertyName, object value);`
  - `propertyName`
    Name of the "IPlantObjectProperty" instance
  - `value`
    New process value of the "IPlantObjectProperty" instance

"Remove" method

Removes a property from the "IPlantObjectPropertySet" instance.

```
void Remove(string propertyName)
```

- `propertyName`
  Name of the property that is being removed.

"Clear" method

Removes all properties from the "IPlantObjectPropertySet" instance.

```
void Clear()
```

"OnPropertySetReadComplete" event

After completion of the read operation of the "ReadAsync" method, the event calls an instance of the "OnPropertySetReadCompleteHandler" delegate.

Declares the event and the event handler for asynchronous read operations.

```
event OnPropertySetReadCompleteHandler OnPropertySetReadComplete
```

"OnPropertySetWriteComplete" event

After completion of the write operation of the "WriteAsync" method, the event calls an instance of the "OnPropertySetWriteCompleteHandler" delegate.

Declares the event and the event handler for asynchronous write operations.

```
event OnPropertySetWriteCompleteHandler OnPropertySetWriteComplete
```

"OnPlantModelPropertySubscriptionNotification" event

After the change of a monitored PropertySet, the event calls an instance of the "OnPlantModelPropertySubscriptionHandler" delegate.

Declares the event and the event handler when changing a PropertySet.

```
event OnPlantModelPropertySubscriptionHandler
OnPlantModelPropertySubscriptionNotification
```

"OnPropertySetReadCompleteHandler" delegate

Specifies the signature of the event handling method for the "OnPropertySetReadComplete" event of an "IPlantObjectPropertySet" instance.

```
void OnPropertySetReadCompleteHandler(
        IPlantObjectPropertySet sender,
        UInt32 errorCode,
        IList<IPlantObjectPropertyValue> values)
```

- `sender`
  Source of the event
- `errorCode`
  Supplies an error code when a global error has occurred.
- `values`
  Event data as a list of "IPlantObjectPropertyValue" instances of the read property.

"OnPropertySetWriteCompleteHandler" delegate

Specifies the signature of the event handling method for the "OnPropertySetWriteComplete" event of an "IPlantObjectPropertySet" instance.

```
void OnPropertySetWriteCompleteHandler(
        IPlantObjectPropertySet sender,
        UInt32 errorCode,
        IList<IPlantObjectPropertyValue> values)
```

- `sender`
  Source of the event
- `errorCode`
  Supplies an error code when a global error has occurred. When the error code is set, `values` is irrelevant.
- `values`
  Event data as a list of "IPlantObjectPropertyValue" instances of the read property.

"OnPlantModelPropertySubscriptionHandler" delegate

Specifies the signature of the event handling method for the "OnPlantModelPropertySubscriptionNotification" event of an "IPlantObjectPropertySet" instance.

```
void OnPlantModelPropertySubcriptionHandler(
        IPlantObjectPropertySet sender,
        IList<IPlantObjectPropertyValue> values)
```

- `sender`
  Source of the event
- `values`
  Event data as a list of the changed "IPlantObjectPropertyValue" instances.

Example

Copy code

```
public void Odk_PlantObjectGetPropertySetReadAsync()
{
    try
    {
        IPlantModel myPlantModel = runtime.GetObject<IPlantModel>();
       string strNodeName = ".hierarchy::RootNodeName\\Node1";    //gets node for specified
Node path
        IPlantObject plantObject = myPlantModel.GetPlantObject(strNodeName);
        System.Console.WriteLine(string.Format("ViewName: {0} Name: {1}",
plantObject.CurrentPlantView,
        plantObject.Name));
        if (plantObject != null)
        {
            ICollection<string> PropNames = null;// get the plant objectproperties by
propeyty names
            IPlantObjectPropertySet plantObjectPropertyset =
plantObject.GetProperties(PropNames);
            if (plantObjectPropertyset != null)
            {
                plantObjectPropertyset.OnPropertySetReadComplete +=
odkPlantModel_onReadComplete; // Read Plant
                Object properties values asynchronously
                plantObjectPropertyset.ReadAsync();
            }
        }
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}
public void odkPlantModel_onReadComplete(IPlantObjectPropertySet sender, UInt32
SystemError, IList<IPlantObjectPropertyValue> Values)
{
    try
    {
        foreach (var value in Values)
        {
            Console.WriteLine("Name {0}", value.Name);
            Console.WriteLine("TimeStamp {0}", value.TimeStamp);Console.WriteLine("Value
{0}", value.Value);
           Console.WriteLine("Quality {0}", value.Quality);Console.WriteLine("Error {0}",
value.Error);
        }
    }
    finally
    {
        if (null != sender)
        {
            sender.Dispose();
        }
    }
}
```

Copy code

Copy code

```
public void odk_plantModelSubscribe()
{
    try
    {
        IPlantModel myPlantmodel = runtime.GetObject<IPlantModel>();
       string strNodeName = ".hierarchy::RootNodeName\\Node1";    //gets node for specified
Node path
        IPlantObject plantObject = myPlantmodel.GetPlantObject(strNodeName);
        System.Console.WriteLine(string.Format("ViewName: {0} Name: {1}",
plantObject.CurrentPlantView,
        plantObject.Name));
        if (plantObject != null)
        {
            ICollection<string> PropNames = null;
            IPlantObjectPropertySet plantObjectPropertyset =
plantObject.GetProperties(PropNames);
            if (plantObjectPropertyset != null)
            {
                // Assign callback function
                plantObjectPropertyset.OnPlantModelPropertySubscriptionNotification +=
                odkPlantModelPropertySet_OnDataChanged;
                plantObjectPropertyset.Subscribe();
            }
        }
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}
public void odkPlantModelPropertySet_OnDataChanged(IPlantObjectPropertySet sender,
IList<IPlantObjectPropertyValue> Values)
{
    try
    {
        foreach (var value in Values)
        {
            Console.WriteLine("Name {0}", value.Name);
            Console.WriteLine("TimeStamp {0}", value.TimeStamp);
            Console.WriteLine("Value {0}", value.Value);
           Console.WriteLine("Quality {0}", value.Quality);Console.WriteLine("Error {0}",
value.Error);
        }
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
    finally
    {
        if (null != sender)
        {
            sender.Dispose();
        }
    }
```

Copy code

```
}
```

IPlantObjectAlarmSubscription

Description

The C# interface "IPlantObjectAlarmSubscription" specifies methods for monitoring alarms of "IPlantObject" instances.

The interface inherits the `Dispose()` method of the "IDisposable" interface of the .NET framework.

Member

The following properties, methods and events are specified in the interface:

"Filter" property

SQL-type string for filtering the result set of active alarms.

```
string Filter { get; set; }
```

All properties of an alarm can be used in the filter string. The filter string can contain operators. Refer to the section Syntax of the alarm filter (Page 7828).

"Language" property

Country identifier of the language of the monitored alarms. See also section Locale IDs of the supported languages (Page 7829).

```
UInt32 Language { get; set; }
```

"IncludeChildren" property

If "true" is transferred, the alarm subscription only applies to the alarms of the "IPlantObject" instance and all its children in the hierarchy. If "false" is transferred, it only applies for the alarms of the "IPlantObject" instance.

```
bool IncludeChildren { get; set; }
```

"Start" method

Subscribe systems for monitoring changes of active alarms.

```
void Start()
```

"Stop" method

Clear monitoring of active alarms.

```
void Stop()
```

"OnPlantObjectSubscribeAlarmHandler" event

Declares the event for the monitoring of alarms of an "IPlantObject" instance.

The event calls an instance of the "OnPlantObjectSubscribeAlarmHandler" delegate.

```
event OnPlantObjectSubscribeAlarmHandler
OnPlantObjectSubscribeAlarmHandler;
```

"OnPlantObjectSubscribeAlarmHandler" delegate

Specifies the signature of the event handling method for the "OnPlantObjectSubscribeAlarmHandler" event of an "IPlantObject" instance.

```
public delegate void OnPlantObjectSubscribeAlarmHandler(
        IPlantObjectAlarmSubscription sender,
        UInt32 systemError,
        string systemName,
        IList<IAlarmResult> values);
```

- `sender`
  Source of the event
- `systemError`
  Supplies an error code when a global error has occurred. When the error code is set, `values` is irrelevant.
- `systemName`
  Name of the runtime system that is subscribed for alarm monitoring by the user.
- `values`
  Event data as a list of "IAlarmResult" instances of the monitored active alarm.

Example

Copy code

```
public void Odk_GetAlarmSubscription()
{
    try
    {
        using (IPlantModel myPlantModel = runtime.GetObject<IPlantModel>())
        {
            string strNodeName = ".hierarchy::RootNodeName\\Node1";    //gets node for
specified Node path
            IPlantObject plantobject = myPlantModel.GetPlantObject(strNodeName);
           IPlantObjectAlarmSubscription alarmsub = plantobject.CreateAlarmSubscription();
  //Assign alarm handler
            if (alarmsub != null)
            {

            sender.Stop();
        }
    }
}
```

20.3.8.8 Interfaces of the Calendar option

ISHCCalendar

Description

The C# interface "ISHCCalendar" specifies the properties and methods of a calendar. The calendar is integrated via an "IPlantObject" instance.

The interface inherits the "Dispose() method of the "IDisposable" interface of the .NET framework and the methods of the "ISHCGetObject" interface

Members

"Settings" property

Reference to an "ISHCCalenderSettings" instance which saves the settings of the calendar.

```
ISHCCalendarSettings Settings { get; }
```

"Category" property

Reference to an "ISHCCategoryProvider" instance with which you access categories of the calendar.

```
ISHCCategoryProvider Category { get; }
```

"DayTemplate" property

Reference to an "ISHCDayTemplatesProvider" instance with which you create, read, update and delete day templates for the calendar.

```
ISHCDayTemplatesProvider DayTemplate { get; }
```

"ShiftTemplate" property

Reference to an "ISHCShiftTemplatesProvider" instance with which you create, read, update and delete shift templates for the calendar.

```
ISHCShiftTemplatesProvider ShiftTemplate { get; }
```

"ActionTemplate" property

Reference to an "ISHCActionTemplatesProvider" instance with which you create, read, update and delete action templates for the calendar.

```
ISHCActionTemplatesProvider ActionTemplate { get; }
```

"Day" property

Reference to an "ISHCDayProvider" instance with which you create, read, update and delete days for the calendar.

```
ISHCDayProvider Day { get; }
```

Example

The following example serves as a basis for the other examples for the C# interfaces of the Calendar option.

It shows how you can obtain the "IPlantObject" instance and also an "ISHCCalendar" instance. The "ISHCCalendar" instance referenced via `calendar` is also used in the other examples.

Copy code

```
using Siemens.Runtime.HmiUnified.SHC;
using Siemens.Runtime.HmiUnified;

ISHCCalendar calendar = null;
// Connect to Runtime
IRuntime runtime = Runtime.Connect();
if (runtime != null)
{
    IPlantModel myPlantModel = runtime.GetObject<IPlantModel>();
    IPlantObject po = myPlantModel.GetPlantObject(".hierarchy::Plant/Unit1");
    if (po != null)
    {
        calendar = po.Calendar();
    }
}
```

ISHCCategory

Description

The C# interface "ISHCCategory" specifies the properties and methods of a time category of the time model.

The interface inherits the "Dispose()" method of the "IDisposable" interface of the .NET framework.

Members

"Name" property

The name of the category

```
string Name { get; }
```

"DisplayNames" property

A dictionary from UInt32/string pairs with the display names and their language code IDs.

```
IDictionary<UInt32, string> DisplayNames { get; }
```

"Descriptions" property

A dictionary from UInt32/string pairs with the descriptions of the category and its language code ID.

```
IDictionary<UInt32, string> Descriptions { get;  }
```

"Color" property

The color of the category

```
Color Color { get; }
```

"Deleted" property

Saves the information on whether an already used category was deleted in Engineering.

```
bool Deleted { get; }
```

Example

```
static void PrintCategory(ISHCCategory category)
{
     if (null != category)
     {
          Console.WriteLine(" \nName:{0} \nColor:{1} \n Deleted:{2}\n", category.Name,
category.Color, category.Deleted);
     }
     IDictionary<uint, string> displayNames = category.DisplayNames;
     foreach (var item in displayNames)
     {
          Console.WriteLine("Language:{0} DisplayName:{1}", item.Key, item.Value);
     }
     IDictionary<uint, string> description = category.Descriptions;
     foreach (var item in description)
     {
          Console.WriteLine("Language:{0} Description:{1}", item.Key, item.Value);
     }
}
```

Locale IDs of the supported languages (Page 7829)

ISHCCategoryProvider

Description

The C# interface "ISHCCategoryProvider" provides you with read access to the "ISHCCategory" instances of an "ISHCCalendar" instance.

Members

"Browse" method

Supplies a collection with the categories of the calendar.

```
IReadOnlyCollection<ISHCCategory> Browse();
```

Example

Copy code

```
IReadOnlyCollection<ISHCCategory> categories = calendar.Category.Browse();
foreach (var cat in categories)
{
    // do something
}
```

ISHCCalendarSettings

Description

The C# interface "ISHCCalendarSettings" specifies properties and methods for access to the calendar settings of an "ISHCCalendar" instance.

The interface inherits the "Dispose()" method of the "IDisposable" interface of the .NET framework.

Members

"PlantObject" property

Reference to the "IPlantObject" instance to which the calendar belongs.

```
string PlantObject { get; }
```

"FirstDayOfWeek" property

Reference to the "ShcWeekDay" instance which is set as the first day of the week.

```
ShcWeekDay FirstDayOfWeek { get; }
```

"FirstWeekOfYear" property

Reference to the "ShcWeekStart" instance which is set as the first week of the year.

```
ShcWeekStart FirstWeekOfYear { get; }
```

"FiscalYearStartDay" property

The first day of the fiscal year

Default setting: 1

```
Byte FiscalYearStartDay { get; }
```

"FiscalYearStartMonth" property

The first month of the fiscal year

Default setting: 1

```
Byte FiscalYearStartMonth { get; }
```

"DayOffset" property

The offset with which the workday begins, calculated from midnight.

Default setting: 0

Maximum value: 24 hours

```
TimeSpan DayOffset { get; }
```

"Workdays" property

Number of workdays

```
UInt32 Workdays { get; }
```

"TimeZone" property

The Microsoft time zone

```
UInt32 TimeZone { get; }
```

Example

```
static void PrintCalendar(ISHCCalendarSettings calendar)
{
     if (null != calendar)
     {
          string cal = string.Format(" \n Workdays: {0} \n FirstDayOfWeek: {1} \n
FirstWeekOfYear: {2} \n FiscalYearStartDay: {3} \n FiscalYearStartMonth: {4} \n DayOffset:
{5} \n PlantObject: {6} \n \n TimeZone:{7} \n", calendar.Workdays, calendar.FirstDayOfWeek,
calendar.FirstWeekOfYear, calendar.FiscalYearStartDay, calendar.FiscalYearStartMonth,
calendar.DayOffset, calendar.PlantObject, calendar.TimeZone);
          Console.WriteLine(cal);
     }
}
```

ISHCTimeSlice

Description

The C# interface "ISHCTimeSlice" specifies the properties and methods of a time slice.

The interface inherits the "Dispose()" method of the "IDisposable" interface of the .NET framework.

Members

"StartTime" property

Time stamp with the start time of the time slice

```
DateTime StartTime { get; set; }
```

"Duration" property

The duration of the time slice

```
TimeSpan Duration { get; set; }
```

"Category" property

The time category of the time slice

```
string Category { get; set; }
```

ISHCDay

Description

The C# interface "ISHCDay" specifies the properties and methods of a day.

The interface inherits the "Dispose()" method of the "IDisposable" interface of the .NET framework.

Members

"Comments" property

A dictionary from UInt32/string pairs with the comments of the "ISHCDay" instance and their language code IDs.

```
IDictionary<UInt32, string> Comments { get; }
```

"StartTime" property

Time stamp with the start time of the "ISHCDay" instance.

```
DateTime StartTime { get; set; }
```

"IsCustomized" property

Saves information on whether the "ISHCDay" instance was edited by users.

```
bool IsCustomized { get; }
```

"DayTemplate" property

The "ISHCDayTemplate" instance from which the "ISHCDay" instance is derived.

```
string DayTemplate { get; set; }
```

"CreateShift" method

Instantiates an "ISHCShift" instance at the "ISHCDay" instance.

```
ISHCShift CreateShift(
       ISHCShiftTemplate shcShiftTemplate,
       TimeSpan startTime);
```

- `shcShiftTemplate`
  Reference to the shift template from which the shift is derived
- `startTime`
  Time stamp with the start time of the "ISHCShift" instance.

"DeleteShift" method

Deletes a shift of the "ISHCDay" instance.

```
void DeleteShift(
       ISHCShift shcShift);
```

- `shcShift`
  Reference to the shift to be deleted

"GetShifts" method

Supplies a list with all the shifts of the "ISHCDay" instance.

```
IReadOnlyList<ISHCShift> GetShifts();
```

"SetComment" method

Adds a new entry to the dictionary of the "Comment" property.

```
void SetComment(
       UInt32 languageId,
       string comment);
```

- `languageId`
  The language code ID of the comment
- `comment`
  A comment

ISHCDayProvider

Description

The C# interface "ISHCDayProvider" provides you with access to the days of an "ISHCCalendar" instance. With the methods of the provider, you can create, read, update and delete days.

Members

"Browse" method

Supplies a collection with the "ISHCDay" instances of the calendar.

```
IReadOnlyCollection<ISHCDay> Browse(
       DateTime startTime, DateTime end);
```

- `startTime`
  Defines the start of the time period whose days are returned.
- `end`
  Defines the end of the time period whose days are returned.

Example:

```
static void ReadDayWithShift()
{
    try
    {
        DateTime start = DateTime.Now.StartOfDay();
        DateTime end = DateTime.Now.EndOfDay();
        end = end.AddDays(3);
        IReadOnlyCollection<ISHCDay> days = calendar.Day.Browse(start, end);
        if (days.Count > 0)
        {
            foreach (var day in days)
            {
                // PrintDays(day);
                if (null != day)
               { string strDays = string.Format("\n StartTime :{0} \n IsCustomized :{1} \n
DayTemplate :{2} ", day.StartTime,                 day.IsCustomized, day.DayTemplate);
                Console.WriteLine(strDays);
                IDictionary<uint, string> Comments = day.Comments;foreach (var item in
Comments)
                {Console.WriteLine("\n Language:{0} DayComment:{1} \n", item.Key,
item.Value);  }
                }

            }
        }
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}
```

"Create" method

Adds new "ISHCDay" instances to the calendar.

```
void  Create(
       IList<ISHCDay> days);
```

- `days`
  List with the new "ISHCDay" instances

Example:

```
static void CreateDayWithShift()
{
    try
    {
        IReadOnlyCollection<ISHCDayTemplate> Daytemplates =
calendar.DayTemplate.Browse(false);
        if (Daytemplates.Count > 0)
        {
            ISHCDayTemplate dayTemplate = Daytemplates.ElementAt(0);
            List<ISHCDay> DayList = new List<ISHCDay>();
            ISHCDay day = calendar.GetObject<ISHCDay>();
            day.DayTemplate = dayTemplate.Name;
            DateTime dtday = DateTime.Now;
            day.StartTime = dtday;
            day.SetComment(1033, "DaywithShift");
            DayList.Add(day);
            calendar.Day.Create(DayList);
            IReadOnlyCollection<ISHCShiftTemplate> ShiftTemplates =
calendar.ShiftTemplate.Browse(false);
            if (ShiftTemplates.Count > 0)
            {
                ISHCShiftTemplate ShiftTemplate = ShiftTemplates.ElementAt(0);
              ISHCShift dayShift = day.CreateShift(ShiftTemplate, new TimeSpan(18, 0, 0));
            }
        }
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}
```

"Update" method

Updates "ISHCDay" instances of the calendar.

```
void Update(
        IList<ISHCDay> days);
```

- `days`
  List of the "ISHCDay" instances to be updated

Example:

```
static void UpdateDayWithShift()
{
    try
    {
        DateTime start = DateTime.Now.StartOfDay();
        DateTime end = DateTime.Now.EndOfDay();
        end = end.AddDays(1);
        IReadOnlyCollection<ISHCDay> days = calendar.Day.Browse(start, end);
        if (days.Count > 0)
        {
            List<ISHCDay> list = new List<ISHCDay>();
            foreach (var day in days)
            {
                IReadOnlyCollection<ISHCShift> shifts = day.GetShifts();
                if (shifts != null)
                {
                    ISHCShift shift = shifts.ElementAt(0);
                    shift.GetTimeSlices().ElementAt(0).Category = "Maintenance";
                }
                list.Add(day);
            }
            calendar.Day.Update(list);
        }
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}
```

"Delete" method

Deletes "ISHCDay" instances of the calendar.

```
void Delete(
      IList<ISHCDay> days);
```

- `days`
  List of "ISHCDay" instances to be deleted

Example:

```
static void DeleteDayWithShift()
{
    try
    {
        DateTime start = DateTime.Now.StartOfDay();
        DateTime end = DateTime.Now.EndOfDay();
        end = end.AddDays(3);
        IReadOnlyCollection<ISHCDay> days = calendar.Day.Browse(start, end);
        if (days.Count > 0)
        {
            List<ISHCDay> list = new List<ISHCDay>();
            foreach (var day in days)
            {
                list.Add(day);
            }
            calendar.Day.Delete(list);
        }
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}
```

ISHCDayTemplate

Description

The C# interface "ISHCDayTemplate" specifies the properties and methods of a day.

The interface inherits the "Dispose()" method of the "IDisposable" interface of the .NET framework.

Members

"Name" property

The name of the "ISHCDayTemplate" instance.

```
string Name { get; set; }
```

"DisplayNames" property

A dictionary from UInt32/string pairs with the display names of the "ISHCDayTemplate" instance and their language code IDs.

```
IDictionary<UInt32, string> DisplayNames { get; }
```

"Descriptions" property

A dictionary from UInt32/string pairs with the descriptions of the "ISHCDayTemplate" instance and their language code IDs.

```
IDictionary<UInt32, string> Descriptions { get; }
```

"Deleted" property

Saves information on whether the day template was deleted by users.

```
bool Deleted { get; }
```

"SetDisplayName" method

Sets the display name of the "ISHCDayTemplate" instance and its language code ID.

```
void SetDisplayName(
       UInt32 languageId,
       string displayName);
```

- `languageId`
  The language code ID of the display name
- `displayName`
  The display name

"SetDescription" method

Sets the description of the "ISHCDayTemplate" instance and its language code ID.

```
void SetDescription(
       UInt32 languageId,
       string description);
```

- `languageId`
  The language code ID
- `description`
  The description

"GetShifts" method

Supplies a collection with the shifts of the "ISHCDayTemplate" instances.

```
IReadOnlyList<ISHCShift> GetShifts();
```

"CreateShift" method

Adds a shift to the "ISHCDayTemplate" instance.

```
ISHCShift CreateShift(
       ISHCShiftTemplate template,
       TimeSpan startTime);
```

- `template`
  Reference to the shift template on which the shift is based.
- `startTime`
  Time stamp with the start time of the shift

"DeleteShift" method

Deletes a shift of the "ISHCDayTemplate" instance.

```
void DeleteShift(
       ISHCShift shift);
```

- `shift`
  Reference to the shift to be deleted

ISHCDayTemplatesProvider

Description

The C# interface "ISHCDayTemplatesProvider" provides you with access to the day templates of an "ISHCCalendar" instance. With the methods of the provider, you can create, read, update and delete day templates.

Members

"Browse" method

Supplies a collection with the "ISHCDayTemplate" instances of the calendar.

```
IReadOnlyCollection<ISHCDayTemplate> Browse(
       bool includeDeleted);
```

- `includeDeleted`
  Saves information on whether the collection also contains the deleted day templates.

Example:

```
static void ReadDayTemplateWithShift()
{
    try
    {
         IReadOnlyCollection<ISHCDayTemplate> dayTemplate =
calendar.DayTemplate.Browse(false);
         if (dayTemplate.Count > 0)
             {
                 foreach (var template in dayTemplate)
                 {
                      PrintDayTemplates(template);
                      ReadShiftsforDayTemplate(template);
                 }
             }
     }
     catch (OdkException ex)
     {
         System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
     }
}
```

"Create" method

Adds new "ISHCDayTemplate" instances to the calendar.

```
void  Create(
       ICollection<ISHCDayTemplate> dayTemplates);
```

- dayTemplates
  Collection with the new "ISHCDayTemplate" instances

Example:

```
static void CreateDayTemplateWithShift()
{
    try
    {
        ISHCDayTemplate Daytemplate = calendar.GetObject<ISHCDayTemplate>();
        if (null != Daytemplate)
        {
            List<ISHCDayTemplate> ListDayTemplate = new List<ISHCDayTemplate>();
            Daytemplate.Name = "DayTemplateName";
            Daytemplate.SetDescription(1033, "DayTemplateDescription");
            Daytemplate.SetDisplayName(1033, "DayTemplateDisplayName");
            ListDayTemplate.Add(Daytemplate);
            calendar.DayTemplate.Create(ListDayTemplate);
            IReadOnlyCollection<ISHCShiftTemplate> ShiftTemplates =
calendar.ShiftTemplate.Browse(false);
            if (ShiftTemplates.Count > 0)
            {
                ISHCShiftTemplate ShiftTemplate = ShiftTemplates.ElementAt(0);
               ISHCShift shift = Daytemplate.CreateShift(ShiftTemplate, new TimeSpan(1, 0,
0));
            }
        }
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}
```

"Update" method

Updates the "ISHCDayTemplate" instances of the calendar.

```
void Update(
        ICollection<ISHCDayTemplate> dayTemplates);
```

- dayTemplates
  Collection with the "ISHCDayTemplate" instances to be updated

Example:

```
static void UpdateDayTemplateWithShift()
{
    try
    {
        IReadOnlyCollection<ISHCDayTemplate> dayTemplate =
calendar.DayTemplate.Browse(false);
        if (dayTemplate.Count > 0)
        {
            List<ISHCDayTemplate> list = new List<ISHCDayTemplate>();
            foreach (var dayTemplates in dayTemplate)
            {
                dayTemplates.Name = "UpdatedDayTemplate";
                dayTemplates.SetDisplayName(1033, "UpdatedDayTemplateDisplayName");
                dayTemplates.SetDescription(1033, "UpdatedDayTemplateDescription");
                IReadOnlyCollection<ISHCShift> shifts = dayTemplates.GetShifts();
                if (shifts != null)
                {
                    ISHCShift shift = shifts.ElementAt(0);
                    shift.Duration = new TimeSpan(6, 0, 0);
                }
                list.Add(dayTemplates);
            }
            calendar.DayTemplate.Update(list);
        }
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}
```

"Delete" method

Deletes "ISHCDayTemplate" instances of the calendar.

```
void Delete(
      ICollection<ISHCDayTemplate> dayTemplates);
```

- `dayTemplates`
  Collection with the "ISHCDayTemplate" instances to be deleted

Example:

```
static void DeleteDayTemplateWithShift()
{
    try
    {
        IReadOnlyCollection<ISHCDayTemplate> dayTemplates =
calendar.DayTemplate.Browse(false);
        if (dayTemplate.Count > 0)
        {
            List<ISHCDayTemplate> list = new List<ISHCDayTemplate>();
            foreach (var dayTemplate in dayTemplates)
            {
                list.Add(dayTemplate);
            }
            calendar.DayTemplate.Delete(list);
        }
    }
    catch (OdkException ex)
    {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
    }
}
```

ISHCShiftTemplate

Description

The C# interface "ISHCShiftTemplate" specifies the properties and methods of a shift.

The interface inherits the "Dispose()" method of the "IDisposable" interface of the .NET framework.

Members

"Name" property

The name of the "ISHCShiftTemplate" instance

```
string Name { get; set; }
```

"DisplayNames" property

A dictionary from UInt32/string pairs with the display names of the "ISHCShiftTemplate" instance and their language code IDs.

```
IDictionary<UInt32, string> DisplayNames { get; }
```

"Descriptions" property

A dictionary from UInt32/string pairs with the descriptions of the "ISHCShiftTemplate" instance and their language code IDs.

```
IDictionary<UInt32, string> Descriptions { get; }
```

"Deleted" property

Saves information on whether the shift template was deleted by users.

```
bool Deleted { get; }
```

"Duration" property

The duration of the "ISHCShiftTemplate" instance.

```
TimeSpan Duration { get; set; }
```

"SetDisplayName" method

Sets the display name of the "ISHCShiftTemplate" instance and its language code ID.

```
void SetDisplayName(
       UInt32 languageId,
       string displayName);
```

- `languageId`
  The language code ID of the display name
- `displayName`
  The display name

"SetDescription" method

Sets the description of the "ISHCShiftTemplate" instance and its language code ID.

```
void SetDescription(
       UInt32 languageId,
       string description);
```

- `languageId`
  The language code ID
- `description`
  The description

"GetTimeSlices" method

Supplies a list with the time slices of the "ISHCShiftTemplate" instance.

```
IReadOnlyList<ISHCTimeSlice> GetTimeSlices();
```

"CreateTimeSlice" method

Adds a time slice to the "ISHCShiftTemplate" instance.

```
void CreateTimeSlice(
       ISHCTimeSlice slice);
```

- `slice`
  Reference to the new time slice

"DeleteTimeSlice" method

Deletes a time slice of the "ISHCShiftTemplate" instance.

```
void DeleteTimeSlice(
       ISHCTimeSlice slice);
```

- `slice`
  Reference to the time slice to be deleted

ISHCShiftTemplatesProvider

Description

The C# interface "ISHCShiftTemplatesProvider" provides you with access to the shift templates of an "ISHCCalendar" instance. With the methods of the provider, you can create, read, update and delete shift templates.

Members

"Browse" method

Supplies a collection with the "ISHCShiftTemplate" instances of the calendar.

```
IReadOnlyCollection<ISHCShiftTemplate> Browse(
       bool includeDeleted);
```

- `includeDeleted`
  Saves information on whether the collection also contains the deleted shift templates.

Example:

```
static void ReadShiftTemplatesWithTimeslice()
{
      try
      {
            Console.WriteLine("ReadShiftTemplate With Timeslice");
            IReadOnlyCollection<ISHCShiftTemplate> template =
calendar.ShiftTemplate.Browse(false);
            if (template.Count > 0)
            {
                  foreach (var shift in template)
                  {
                        PrintShiftTemplates(shift);
                        ReadTimeslicesforShiftTemplate(shift);
                  }
            }
      }
      catch (OdkException ex)
      {
            System.Console.WriteLine(string.Format("OdkException occurred {0}",
ex.Message));
      }
}
```

"Create" method

Adds new "ISHCShiftTemplate" instances to the calendar.

```
void Create(
       ICollection<ISHCShiftTemplate> shiftTemplates);
```

- `shiftTemplates`
  Collection with the new "ISHCShiftTemplate" instances of the calendar.

Example:

```
static void CreateShiftTemplateWithTimeSlice()
{
      try
      {
         using (ISHCShiftTemplate pShiftTemplate = calendar.GetObject<ISHCShiftTemplate>())
            {
                pShiftTemplate.Name = "ShiftTemplateName";
                pShiftTemplate.SetDisplayName(1033, "ShiftTemplateDisplayName");
                pShiftTemplate.SetDescription(1033, "ShiftTemplateDescriptions");
                pShiftTemplate.Duration = new TimeSpan(8, 0, 0);
                List<ISHCShiftTemplate> ShiftList = new List<ISHCShiftTemplate>();
                ShiftList.Add(pShiftTemplate);
                calendar.ShiftTemplate.Create(ShiftList);
                IReadOnlyCollection<ISHCCategory> categories = calendar.Category.Browse();
                if (categories.Count > 0)
                {
                    ISHCCategory pCat = categories.ElementAt(0);
                    ISHCTimeSlice pTimeSlice = calendar.GetObject<ISHCTimeSlice>();
                    pTimeSlice.StartTime = DateTime.Now.StartOfDay();
                    pTimeSlice.Duration = new TimeSpan(3, 0, 0);
                    pTimeSlice.Category = pCat.Name;
                    pShiftTemplate.CreateTimeSlice(pTimeSlice);
                }
            }
      }
      catch (OdkException ex)
      {
            System.Console.WriteLine(string.Format("OdkException occurred {0}",
ex.Message));
      }
}
```

"Update" method

Updates "ISHCShiftTemplate" instances of the calendar.

```
void Update(
       ICollection<ISHCShiftTemplate> shiftTemplates);
```

- `shiftTemplates`
  Collection with the "ISHCShiftTemplate" instances to be updated

Example:

```
static void UpdateShiftTemplateWithTimeslice()
{
      try
      {
            IReadOnlyCollection<ISHCShiftTemplate> shiftTemplates =
calendar.ShiftTemplate.Browse(false);
            List<ISHCShiftTemplate> list = new List<ISHCShiftTemplate>();
            IReadOnlyCollection<ISHCCategory> categories = calendar.Category.Browse();
            ISHCCategory pCat = categories.ElementAt(1);
            foreach (var shifttemplate in shiftTemplates)
            {
                  shifttemplate.Name = "UpdateShiftTemplate";
                  shifttemplate.SetDisplayName(1033, "Updated DisplayName");
                  shifttemplate.SetDescription(1033, "UpdatedDescription");
                  shifttemplate.Duration = new TimeSpan(10, 0, 0);
                  list.Add(shifttemplate);
                  IReadOnlyCollection<ISHCTimeSlice> Timeslices =
shifttemplate.GetTimeSlices();
                  if (Timeslices.Count > 0)
                  {
                        ISHCTimeSlice timeslice = Timeslices.ElementAt(0);
                        timeslice.Duration = new TimeSpan(5, 0, 0);
                        timeslice.Category = pCat.Name;
                  }
            }
            calendar.ShiftTemplate.Update(list);
      }
      catch (OdkException ex)
      {
            System.Console.WriteLine(string.Format("OdkException occurred {0}",
ex.Message));
      }
}
```

"Delete" method

Deletes "ISHCShiftTemplate" instances of the calendar.

```
void Delete(
       ICollection<ISHCShiftTemplate> shiftTemplates);
```

- `shiftTemplates`
  Collection with the "ISHCShiftTemplate" instances of the calendar to be deleted.

Example:

```
static void DeleteShiftTemplateWithTimeslice()
{
      try
      {
            IReadOnlyCollection<ISHCShiftTemplate> shiftTemplates =
calendar.ShiftTemplate.Browse(false);
            if (shiftTemplates.Count > 0)
            {
                  List<ISHCShiftTemplate> list = new List<ISHCShiftTemplate>();
                  foreach (var shifttemplate in shiftTemplates)
                  {
                        list.Add(shifttemplate);
                  }
                  calendar.ShiftTemplate.Delete(list);
            }
      }
      catch (OdkException ex)
      {
            System.Console.WriteLine(string.Format("OdkException occurred {0}",
ex.Message));
      }
}
```

ISHCShift

Description

The C# interface "ISHCShift" specifies the properties and methods of a shift.

The interface inherits the "Dispose()" method of the "IDisposable" interface of the .NET framework.

Members

"StartTime" property

Time stamp with the start time of the "ISHCShift" instance.

```
DateTime StartTime { get; set; }
```

"Duration" property

The duration of the "ISHCShift" instance.

```
TimeSpan Duration { get; set; }
```

"ShiftTemplate" property

The shift template of the "ISHCShift" instance.

```
string ShiftTemplate { get; }
```

"IsCustomized" property

Saves information on whether the "ISHCShift" instance was edited by users.

```
bool IsCustomized { get; }
```

"DeltaKind" property

Saves information on how the time slices of the "ISHCShift" instance deviate from the shift template.

```
ShcDeltaType DeltaKind { get; }
```

The enumeration "ShcDeltaType" can contain the following values:

- `Added` (0)
- `Modified` (1)
- `Deleted` (2)

"ShiftId" property

Saves the ShiftID of the "ISHCShift" instance.

```
UInt32 ShiftId { get; set; }
```

"Comments" property

A dictionary from UInt32/string pairs with the descriptions of the "ISHCShift" instance and their language code IDs.

```
IDictionary<UInt32, string> Comments { get; }
```

"GetTimeSlices" method

Supplies a collection with the time slices of the "ISHCShift" instances.

```
IReadOnlyList<ISHCTimeSlice> GetTimeSlices();
```

"CreateTimeSlice" method

Adds a time slice to the "ISHCShift" instance.

```
void CreateTimeSlice(
       ISHCTimeSlice slice);
```

- `slice`
  Reference to the new time slice

"DeleteTimeSlice" method

Deletes a time slice of the "ISHCShift" instance.

```
void DeleteTimeSlice(
       ISHCTimeSlice slice);
```

- `slice`
  Reference to the time slice to be deleted

"SetComment" method

Adds a comment with language code ID to the "Comments" property.

```
void SetComment(
       UInt32 languageId,
       string comment);
```

- `languageId`
  The language code ID of the comment
- `comment`
  The comment

"CreateAction" method

Adds an action to the "ISHCShift" instance.

```
ISHCAction CreateAction(
       ISHCActionTemplate actionTemplate,
       TimeSpan offset);
```

- `actionTemplate`
  The action template of the new action
- `offset`
  The offset for the anchor point of the action, in relation to the starting point of the shift. Positive and negative value allowed.

Example:

```
static void CreateActionUsingShift()
{
     try
     {
          DateTime start = DateTime.Now.StartOfDay();
          DateTime end = DateTime.Now.EndOfDay();
          end = end.AddDays(3);
          ISHCShift Shift = calendar.Day.Read(start,
end).ElementAt(0).GetShifts().ElementAt(0);
          if (Shift != null)
          {
               ISHCAction Action =
Shift.CreateAction(calendar.ActionTemplate.Read(false).ElementAt(0), new TimeSpan(5, 0,
0));
          }
     }
     catch (OdkException ex)
     {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
     }
}
```

"DeleteAction" method

Deletes an action of the "ISHCShift" instance.

```
void DeleteAction(ISHCAction shcAction);
```

- `shcAction`
  Reference to the action to be deleted

"GetActions" method

Supplies a list with the actions of the "ISHCShift" instance.

```
IReadOnlyList<ISHCAction> GetActions();
```

Example:

```
static void ReadActionUsingShift()
{
     try
     {
          DateTime start = DateTime.Now.StartOfDay();
          DateTime end = DateTime.Now.EndOfDay();
          end = end.AddDays(3);
          ISHCShift Shift = calendar.Day.Read(start,
end).ElementAt(0).GetShifts().ElementAt(0);
          if (Shift != null)
          {
               IReadOnlyList<ISHCAction> action = Shift.GetActions();
               if (action != null)
               {
                    ISHCAction actions = action.ElementAt(0);
                    string Action = string.Format("\n Offset:{0} \n IsCustomized:
{1} ,actionTemplate:{2}", actions.Offset, actions.IsCustomized, actions.ActionTemplate);
                    System.Console.WriteLine(Action);
               }
          }
     }
     catch (OdkException ex)
     {
         System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
     }
}
```

ISHCAction

Description

The C# interface "ISHCAction" specifies the properties and methods of an action.

The interface inherits the "Dispose()" method of the "IDisposable" interface of the .NET framework.

Members

"Offset" property

The offset for the anchor point of the "ISHCAction" instance in 100 nanoseconds in relation to the start point of its shift instance. Positive and negative value allowed.

```
TimeSpan Offset { get; set; }
```

"ActionTemplate" property

The action template of the "ISHCAction" instance

```
string ActionTemplate { get; }
```

"IsCustomized" property

Saves information on whether the "ISHCAction" instance was edited by users.

```
bool IsCustomized { get; }
```

"GetElements" method

Supplies a list with the action elements of the "ISHCAction" instance.

```
IReadOnlyList<ISHCActionElement> GetElements();
```

ISHCActionElement

Description

The C# interface "ISHCActionElement" specifies the properties and methods of an action element of an "ISHCAction" instance.

The interface inherits the "Dispose()" method of the "IDisposable" interface of the .NET framework.

Members

"ElementType" property

The type of the "ISHCActionElement" instance.

```
ShcActionElementType ElementType { get; }
```

The enumeration "ShcActionElementType" can contain the following values:

- `Tag` (0)
  The action element controls a tag.

"Enabled" property

Saves the information on whether the "ISHCActionElement" instance is activated.

```
bool Enabled { get; set; }
```

"Offset" property

The offset of the "ISHCActionElement" instance in 100 nanoseconds in relation to the anchor point of its action. Positive and negative value allowed.

```
TimeSpan Offset { get; set; }
```

"Value" property

Value of the tag controlled by the "ISHCActionElement" instance

```
object Value { get; set; }
```

"ElementName" property

Name of the tag controlled by the "ISHCActionElement" instance

```
string ElementName { get; set; }
```

ISHCActionTemplate

Description

The C# interface "ISHCActionTemplate" specifies the properties and methods of the action template of an "ISHCAction" instance.

The interface inherits the "Dispose()" method of the "IDisposable" interface of the .NET framework.

Members

"Name" property

The name of the "ISHCActionTemplate" instance.

```
string Name { get; set; }
```

"DisplayNames" property

A dictionary from UInt32/string pairs with the display names of the "ISHCActionTemplate" instance and their language code IDs.

```
IDictionary<UInt32, string> DisplayNames { get; }
```

"Deleted" property

Saves information on whether the action template was deleted by users.

```
bool Deleted { get; }
```

"Descriptions" property

A dictionary from UInt32/string pairs with the descriptions of the "ISHCActionTemplate" instance and their language code IDs.

```
IDictionary<UInt32, string> Descriptions { get; }
```

"SetDisplayName" method

Sets the display name of the "ISHCActionTemplate" instance and its language code ID.

```
void SetDisplayName(
       UInt32 languageId,
       string displayName);
```

- `languageId`
  The language code ID of the display name
- `displayName`
  The display name

"SetDescription" property

Sets the description of the "ISHCActionTemplate" instance and its language code ID.

```
void SetDescription(
       UInt32 languageId,
       string description);
```

- `languageId`
  The language code
- `IDdescription`
  The description

"CreateElement" property

Adds an "ISHCActionTemplateElement" instance to the "ISHCActionTemplate" instance.

```
void CreateElement(
       ISHCActionTemplateElement actiontemplateElement);
```

- `actiontemplateElement`
  Reference to the new action template element

"DeleteElement" property

Deletes an "ISHCActionTemplateElement" instance of the "ISHCActionTemplate" instance.

```
void DeleteElement(
       ISHCActionTemplateElement actiontemplateElement);
```

- `actiontemplateElement`
  Reference to the action template element to be deleted

"GetElements" property

Supplies a list with action template elements of the "ISHCActionTemplate" instances.

```
IReadOnlyList<ISHCActionTemplateElement> GetElements();
```

See also

Locale IDs of the supported languages (Page 7829)

ISHCActionTemplateElement

Description

```

"Value" property

Value of the tag controlled by the "ISHCActionTemplateElement" instance.

```
object Value { get; set; }
```

"ElementName" property

Name of the tag controlled by the "ISHCActionTemplateElement" instance.

```
string ElementName { get; set; }
```

ISHCActionTemplatesProvider

Description

The C# interface "ISHCActionTemplatesProvider" provides you with access to the action templates of an "ISHCCalendar" instance. With the methods of the provider, you can create, read, update and delete action templates.

Members

"Browse" method

Supplies a collection with the "ISHCActionTemplate" instances of the calendar.

```
IReadOnlyCollection<ISHCActionTemplate> Browse(
       bool includeDeleted);
```

- `includeDeleted`
  Saves information on whether the collection also contains the deleted action templates.

Example:

```
static void ReadActionTemplate()
{
     try
     {
          Console.WriteLine("ReadActionTemplate");
          IReadOnlyCollection<ISHCActionTemplate> actionTemplate =
calendar.ActionTemplate.Browse(false);
          foreach (var template in actionTemplate)
          {
               PrintActionTemplates(template);
          }
     }
     catch (OdkException ex)
     {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
     }
}
```

"Create" method

Adds new "ISHCActionTemplate" instances to the calendar.

```
void  Create(
       ICollection<ISHCActionTemplate> actionTemplates);
```

- `actionTemplates`
  Collection with the new "ISHCActionTemplate" instances

Example:

```
static void CreateActionTemplateWithActionTemplateElement()
{
     try
     {
          ISHCActionTemplate pActionTemplate = calendar.GetObject<ISHCActionTemplate>();
          if (pActionTemplate != null)
          {
               pActionTemplate.Name = "ActionTemplate";
               pActionTemplate.SetDisplayName(1033, "ActionDisplayName");
               pActionTemplate.SetDescription(1033, "ActionDescription");
               List<ISHCActionTemplate> ActionList = new List<ISHCActionTemplate>();
               ActionList.Add(pActionTemplate);
               calendar.ActionTemplate.Create(ActionList);
               ISHCActionTemplateElement pActionTemplateElement =
calendar.GetObject<ISHCActionTemplateElement>();
               if (pActionTemplateElement != null)
               {
                    pActionTemplateElement.ElementName = "HMI_RT_1::Unit1.Member_1";
                    pActionTemplateElement.Value = false;
                    pActionTemplateElement.Offset = new TimeSpan(4, 0, 0);
                    pActionTemplate.CreateElement(pActionTemplateElement);
               }
          }
     }
     catch (OdkException ex)
     {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
     }
}
```

"Update" method

Updates "ISHCActionTemplate" instances of the calendar.

```
void Update(
        ICollection<ISHCActionTemplate> actionTemplates);
```

- `actionTemplates`
  Collection with the "ISHCActionTemplate" instances to be updated

Example:

```
static void UpdateActionTemplateWithActionTemplateElement()
{
     IReadOnlyCollection<ISHCActionTemplate> actionTemplates =
calendar.ActionTemplate.Browse(false);
     List<ISHCActionTemplate> list = new List<ISHCActionTemplate>();
     foreach (var actionTemplate in actionTemplates)
     {
          actionTemplate.Name = "UpdatedActionTemplate";
          actionTemplate.SetDisplayName(1033, "UpdatedDisplayName ");
          actionTemplate.SetDescription(1033, "UpdatedDescription");
          IReadOnlyCollection<ISHCActionTemplateElement> action =
actionTemplate.GetElements();
          ISHCActionTemplateElement templateElement = action.ElementAt(0);
          templateElement.Offset = new TimeSpan(6, 0, 0);
          list.Add(actionTemplate);
     }
     calendar.ActionTemplate.Update(list);
}
```

"Delete" method

Deletes "ISHCActionTemplate" instances of the calendar.

```
void Delete(
      ICollection<ISHCActionTemplate> actionTemplates);
```

- `actionTemplates`
  Collection with the "ISHCActionTemplate" instances to be deleted

Example:

```
static void DeleteActionTemplateWithActionTemplateElement()
{
     try
     {
          IReadOnlyCollection<ISHCActionTemplate> actionTemplates =
calendar.ActionTemplate.Browse(false);
          if (actionTemplates.Count > 0)
          {
               List<ISHCActionTemplate> list = new List<ISHCActionTemplate>();
               foreach (var actionTemplate in actionTemplates)
               {
                    list.Add(actionTemplate);
               }
               calendar.ActionTemplate.Delete(list);
          }
     }
     catch (OdkException ex)
     {
        System.Console.WriteLine(string.Format("OdkException occurred {0}", ex.Message));
     }
}
```

IContextLogging

Description

The C# interface "IContextLogging" defines events and methods for creating and reading "IContextDefinition" instances as well as for starting, stopping, monitoring and reading their "ILoggedContext" instances. You can use "ILoggedContext" instances to filter runtime data, for example, for alarms that fall within the time period of a particular "ILoggedContext" instance.

The interface inherits the Dispose() method of the "IDisposable" interface of the .NET framework.

The methods trigger an exception in case of an error.

Members

"CreateContextDefinitions" method

Creates ContextDefinitions in the database.

```
void CreateContextDefinitions(ICollection<IContextDefinition>
contextDefinitions)
```

- `contextDefinitions`:
  Collection with "IContextDefinition" instances

"ReadContextDefinitions" method

Reads ContextDefinitions from the database. The instances can be filtered by plant object and HMIContextProviderType .

```
void ReadContextDefinitions(ICollection<string> plantViewPaths =
null, ICollection<HmiContextProviderType> providerTypes = null,
HmiSortingMode sortingMode = HmiSortingMode.Ascending)
```

- `plantViewPaths`:
  Limits the read operation to "IContextDefinition" instances from this collection of plant objects.
- (optional) `providerTypes`:
  Limits the read operation to "IContextDefinition" instances with HmiContextProvider types from this collection.
  The enumeration "HmiContextProviderType" can contain the following values:
  - NoContext = 0
  - Calendar = 1
    For "IContextDefinition" instances generated by the PI Option Calendar.
  - PerformanceInsightMachineState = 2
    For "IContextDefinition" instances generated by the PI Option Performance Insight.
  - LineCoordinator = 3
    For "IContextDefinition" instances generated by the PI Option Line Coordinator.
  - UserDefined = 5
    It is a user-defined "IContextDefinition" instance, created by ODK, for example.
- (optional) `sortingMode`:
  The "HmiSortingMode" according to which the read "IContextDefinition" instances are sorted.
  The enumeration "HmiSortingMode" can contain the following values:
  - Ascending = 1
    Default setting
  - Descending = 2

"ReadContexts" method

Reads "ILoggedContext" instances of a specific time period. The instances can be filtered using a "IContextFilter" instance.

```
void ReadContexts(DateTime start, DateTime end,
IContextFilter ContextFilter=null, HmiSortingMode sortingMode =
HmiSortingMode.Ascending)
```

- `start`:
  The start time of the period within which the "ILoggedContext" instances must lie.
- `end`:
  The end time of the period within which the "ILoggedContext" instances must lie.

- (optional) `ContextFilter`:
  The "IContextFilter" instance whose filter settings are used.
- (optional) `sortingMode`:
  The "HmiSortingMode" according to which the read "ILoggedContext" instances are sorted.
  The enumeration "HmiSortingMode" can contain the following values:
  - Ascending = 1
    Default setting
  - Descending = 2

"StartContext" method

Creates a new "ILoggedContext" instance for a "IContextDefinition" instance.

```
void StartContext(string contextName, HmiContextProviderType
providerType, string plantViewPath, object contextValue, DateTime
startTime, UInt32 qualityCode)
```

- `contextName`:
  The name of the "IContextDefinition" instance for which the context log entry is created.
- (optional) `providerType`:
  The HmiContextProviderType that the "IContextDefinition" instance of the context log entry must have.
  The enumeration "HmiContextProviderType" can contain the following values:
  - NoContext = 0
  - Calendar = 1
    For "IContextDefinition" instances generated by the PI Option Calendar.
  - PerformanceInsightMachineState = 2
    For "IContextDefinition" instances generated by the PI Option Performance Insight.
  - LineCoordinator = 3
    For "IContextDefinition" instances generated by the PI Option Line Coordinator.
  - UserDefined = 5
    It is a user-defined "IContextDefinition" instance, created by ODK, for example.
- `plantViewPath`:
  Path to an "IPlantObject" instance
  E.g.: ".hierarchy::PlantView/Ln_1/M_1"
  Is used in combination with `contextName` for unique identification of the "IContextDefinition" instance.
- `contextValue`:
  The context value of the context log entry
- `startTime`:
  The start time of the new context log entry
- `qualityCode`:
  The QualityCode of the context value of the context log entry

"StopContext" method

Stops the currently running "ILoggedContext" instance of an "IContextDefinition" instance.

```
void StopContext(string contextName, HmiContextProviderType
providerType, string plantViewPath, DateTime endtime)
```

- `contextName`:
  The name of the "IContextDefinition" instance whose context log entry is stopped.
- (optional) `providerType`:
  The HmiContextProviderType that the "IContextDefinition" instance of the context log entry must have.
  The enumeration "HmiContextProviderType" can contain the following values:
  - NoContext = 0
  - Calendar = 1
    For "IContextDefinition" instances generated by the PI Option Calendar.
  - PerformanceInsightMachineState = 2
    For "IContextDefinition" instances generated by the PI Option Performance Insight.
  - LineCoordinator = 3
    For "IContextDefinition" instances generated by the PI Option Line Coordinator.
  - UserDefined = 5
    It is a user-defined "IContextDefinition" instance, created by ODK, for example.
- `plantViewPath`:
  Path to an "IPlantObject" instance
  E.g.: ".hierarchy::PlantView/Ln_1/M_1"
  Is used in combination with `contextName` for unique identification of the "IContextDefinition" instance.
- `endtime`:
  End time of the context log entry

"Add" method

Adds a "IContextDefintion" instance to a vector. The methods Clear(), Subscribe() and CancelSubscription() can be called for the instances of the vector.

```
void Add(string contextName, HmiContextProviderType providerType,
string plantViewPath)
```

- `contextName`:
  The name of the "IContextDefintion" instance
- `providerType`:
  The HmiContextProviderType of the "IContextDefintion" instance
  The enumeration "HmiContextProviderType" can contain the following values:
  - NoContext = 0
  - Calendar = 1
    For "IContextDefinition" instances generated by the PI Option Calendar.
  - PerformanceInsightMachineState = 2
    For "IContextDefinition" instances generated by the PI Option Performance Insight.
  - LineCoordinator = 3
    For "IContextDefinition" instances generated by the PI Option Line Coordinator.
  - UserDefined = 5
    It is a user-defined "IContextDefinition" instance, created by ODK, for example.
- `plantViewPath`:
  Path to an "IPlantObject" instance
  E.g.: ".hierarchy::PlantView/Ln_1/M_1"
  Is used in combination with `contextName` for unique identification of the "IContextDefinition" instance.

"Clear" method

Deletes the "IContextDefintion" instances added via `Add()` from the vector.

```
void Clear()
```

"Subscribe" method

Subscribes the "IContextDefinition" instances added to the vector via `Add()` for monitoring.

```
void Subscribe()
```

"CancelSubscription" method

Unsubscribes the "IContextDefinition" instances added to the vector with `Add()` from monitoring.

```
void CancelSubscribe()
```

"OnContextDefinitionCreate" event

The event calls the delegate "OnContextDefinitionCreateDelegate" after the creation of ContextDefinitions.

Declares the event and the event handler for creating "IContextDefinition" instances.

```
event OnContextDefinitionCreateDelegate OnContextDefinitionCreate;
```

"OnContextDefinitionReadReply" event

After reading the ContextDefinitions, the event calls the "OnContextDefinitionReadReplyDelegate" delegate.

Declares the event and the event handler for reading "IContextDefinition" instances.

```
event OnContextDefinitionReadReplyDelegate
OnContextDefinitionReadReply;
```

"OnLoggedContextReadReply" event

After reading the LoggedContexts, the event calls the "OnContextReadReplyDelegate" delegate.

Declares the event and the event handler for reading "ILoggedContext" instances.

```
event OnContextReadReplyDelegate OnLoggedContextReadReply;
```

"OnContextDataChanged" event

Event calls the delegate "OnContexDataChangedHandler" when starting or stopping a monitored "ILoggedContext" instance.

Declares the event and the event handler for monitoring "ILoggedContext" instances.

```
event OnContexDataChangedHandler OnContextDataChanged;
```

"OnContextDefinitionCreateDelegate" delegate

Specifies the signature of the event handling method for the "OnContextDefinitionCreate" event of the "IContextLogging" interface.

```
public delegate void
OnContextDefinitionCreateDelegate(IContextLogging sender,
        UInt32 globalError,
        string systemName,
        List<IContextError> errors,
        bool completed)
```

- `sender`:
  Source of the event
- `globalError`:
  Global ErrorCode when a global error occurs during the call. All other parameters are invalid in this case.
- `systemName`:
  Name of the system on which the ContextDefinitions have been created.
- `errors`:
  List with the instance-specific errors that were generated when the ContextDefinitions were created.
- `completed`:
  Status of the asynchronous transfer:
  - True: All ContextDefinitions have been notified.
  - False: Additional notifications are expected.

"OnContextDefinitionReadReplyDelegate" delegate

Specifies the signature of the event handling method for the "OnContextDefinitionReadReply" event of the "IContextLogging" interface.

```
public delegate void
OnContextDefinitionReadReplyDelegate(IContextLogging sender,
        UInt32 globalError,
        string systemName,
        IList<IContextDefinition> contextDefinitionData,
        bool completed)
```

- `sender`:
  Source of the event
- `globalError`:
  Global ErrorCode when a global error occurs during the call. All other parameters are invalid in this case.
- `systemName`:
  Name of the system on which the ContextDefinitions have been created.
- `contextDefinitionData`:
  List of read "IContextDefinition" instances
- `completed`:
  Status of the asynchronous transfer:
  - True: All ContextDefinitions have been notified.
  - False: Additional notifications are expected.

"OnContextReadReplyDelegate" delegate

Specifies the signature of the event handling method for the "OnLoggedContextReadReply" event of the "IContextLogging" interface.

```
public delegate void OnContextReadReplyDelegate(IContextLogging
sender,
        UInt32 globalError,
        string systemName,
        IList<ILoggedContext> loggedContexts,
        bool completed)
```

- `sender`:
  Source of the event
- `globalError`:
  Global ErrorCode when a global error occurs during the call. All other parameters are invalid in this case.
- `systemName`:
  Name of the system on which the "ILoggedContext" instances have been created.
- `loggedContexts`:
  List with "ILoggedContext" instances that were started or stopped.
- `completed`:
  Status of the asynchronous transfer:
  - True: All ContextDefinitions have been notified.
  - False: Additional notifications are expected.

"OnContexDataChangedHandler" delegate

Specifies the signature of the event handling method for the "OnContextDataChanged" event of the "IContextLogging" interface.

```
public delegate void OnContexDataChangedHandler(IContextLogging
sender,
        IList<ILoggedContext> loggedContexts)
```

- `sender`:
  Source of the event
- `loggedContexts`:
  List with "ILoggedContext" instances

Example

Copying code

```
public void CreateContextDefinitions()
{
     Console.WriteLine("CreateContextDefinitions \n");
     var contextLogging = _runtime.GetObject<IContextLogging>();
     List<IContextDefinition> contextDefnitions = new List<IContextDefinition>();
     for (int i = 0; i < 5; i++)
     {
          var contextDefinition = _runtime.GetObject<IContextDefinition>();
          contextDefinition.PlantViewPath = ".hierarchy::Plant/Node1_1";
          contextDefinition.DataType = HmiContextDataType.DInt;
          Dictionary<UInt32, string> displayLanguages = new Dictionary<uint, string>();
          displayLanguages[1033] = "english";
          displayLanguages[1031] = "deutsch";
          contextDefinition.DisplayNames = displayLanguages;
          Random rnd = new Random();
          int num = rnd.Next(1, 1000);
          contextDefinition.Name = "CD_" + num + i.ToString();
          contextDefnitions.Add(contextDefinition);
          contextLogging.OnContextDefinitionCreate +=
ContextLogging_OnContextDefinitionCreate;
          contextLogging.CreateContextDefinitions(contextDefnitions);
          _event.WaitOne();
          _event.Reset();
          contextLogging.Dispose();
     }
}
```

Copying code

```
private void ContextLogging_OnContextDefinitionCreate(IContextLogging sender, UInt32
globalError, string systemName, IList<IContextError> errors, bool completed)
{
    if (globalError != 0)
    {
        Console.WriteLine("System Name:{0} Error:{1}", systemName, globalError);
    }
    else
    {
        if (null != errors)
        {
            foreach (var error in errors)
            {
                Console.WriteLine("ContextName:{0} Error:{1}", error.Name, error.Error);
                Console.WriteLine();
            }
        }
    }
}
```

Copying code

```
public void ReadContextDefinitionsWithFilter()
{
    Console.WriteLine("ReadContextDefinitionsWithFilter \n");
    var contextLogging = _runtime.GetObject<IContextLogging>();
    contextLogging.OnContextDefinitionReadReply +=
OnContextDefinitionReadReplyForContextLogging;
    List<string> plantobjectsfilter = new List<string>();
    plantobjectsfilter.Add(".hierarchy::Plant/Node1_1");
    List<HmiContextProviderType> contextProviderType = new List<HmiContextProviderType>();
    contextProviderType.Add(HmiContextProviderType.UserDefined);
    contextLogging.ReadContextDefinitions(plantViewPaths: plantobjectsfilter,
providerTypes: contextProviderType, sortingMode: HmiSortingMode.Ascending);
    _event.WaitOne();
    _event.Reset();
    contextLogging.Dispose();
}
```

Copying code

```
public void StartContext()
{
    Console.WriteLine("StartContext \n");
    var contextLogging = _runtime.GetObject<IContextLogging>();
    startDt = System.DateTime.Now;
    object value = "Orange Juice";
    uint quality = 192;
    var strContextName = "ContextName_" + strContext_Unique_Num;
    var providerType = HmiContextProviderType.UserDefined;
    IPlantObject plantObject = ".hierarchy::PlantView/Ln_1/M_1";
    var plantViewPath = ".hierarchy::Plant/Node1_1";
    contextLogging.StartContext(strContextName, providerType, plantViewPath, value,
startDt, quality);
}
```

Copying code

```
public void StopContext()
{
    Console.WriteLine("StopContext \n");
    var contextLogging = _runtime.GetObject<IContextLogging>();
    endDt = System.DateTime.Now;
    var strContextName = "ContextName_" + strContext_Unique_Num;
    var providerType = HmiContextProviderType.UserDefined;
    contextLogging.StopContext(strContextName, providerType, endDt);
}
```

Copying code

```
void OnContextDefinitionReadReplyForContextLogging(IContextLogging sender, UInt32
globalErrors, string systemName, IList<IContextDefinition> contextDefinitions, bool
completed)
{
    if (globalErrors != 0)
    {
     Console.WriteLine("System Name:{0} Error:{1}", systemName, globalErrors);
    }
    else
    {
        if (null != contextDefinitionData)
        {
            foreach (var cd in contextDefinitionData)
            {
                Console.WriteLine("PlantViewPath:{0} Name:{1} Datatype:{2} Error:{3}",
cd.PlantViewPath, cd.Name, cd.DataType, cd.Error);
                Console.WriteLine();
            }
        }
    }
}
```

Copying code

```
void OnLoggedContextReadReplyForContextLogging(IContextLogging sender, UInt32
globalErrors, string systemName, IList<ILoggedContext> loggedContexts, bool completed)
{
    if (globalErrors != 0)
    {
        Console.WriteLine("System Name:{0} Error:{1}", systemName, globalErrors);
    }
    else
    {
        if (null != loggedContexts)
        {
            foreach (var lc in loggedContexts)
            {
               Console.WriteLine("StartTime:{0} EndTime:{1} Value:{2} Quality:{3} Error:
{4}", lc.StartTime, lc.EndTime, lc.Value, lc.Quality, lc.Error);
               Console.WriteLine();
            }
        }
    }
}
```

Copying code

```
public void Subscribe()
{
    Console.WriteLine("Subscribe \n");
    var contextLogging = _runtime.GetObject<IContextLogging>();
    contextLogging.OnContextDataChanged += OnContextDataChangedForContextLogging;
    CreateContextDefinition();
    var name = "ContextName_" + strContext_Unique_Num;
    var providerType = HmiContextProviderType.UserDefined;
    contextLogging.Add(name, providerType);
    contextLogging.Subscribe();
    StartContext();
    StopContext();
    contextLogging.CancelSubscribe();
    contextLogging.Dispose();
}
```

IContextDefinition

Description

The C# interface "IContextDefinition" specifies properties for the definition of "IContextDefinition" instances. "ILoggingContext" instances can be created using the Start() and Stop() methods based on an "IContextDefiniton" instance.

The interface inherits the Dispose() method of the "IDisposable" interface of the .NET framework.

Members

"PlantViewPath" property

Sets the path to the plant object of the "IContextDefinition" instance

```
string PlantViewPath { get; set; }
```

Example: ".hierarchy::Plant/Station"

"ProviderType" property

The source that creates the instance.

Is used together with "Name" to uniquely identify a "IContextDefinition" instance.

```
HmiContextProviderType ProviderType { get; }
```

The enumeration "HmiContextProviderType" can contain the following values:

(optional) `providerType`:
The HmiContextProviderType that the "IContextDefinition" instance of the context log entry must have.

The enumeration "HmiContextProviderType" can contain the following values:

- NoContext = 0
- Calendar = 1
  For "IContextDefinition" instances generated by the PI Option Calendar.
- PerformanceInsightMachineState = 2
  For "IContextDefinition" instances generated by the PI Option Performance Insight.
- LineCoordinator = 3
  For "IContextDefinition" instances generated by the PI Option Line Coordinator.
- UserDefined = 5
  It is a user-defined "IContextDefinition" instance, created by ODK, for example.

"Name" property

The name of the "IContextDefinition" instance

Is used together with "ProviderType" to uniquely identify a "IContextDefinition" instance.

```
string Name { get; set;}
```

"DisplayNames" property

The display name of the "IContextDefinition" instance

```
IDictionary<UInt32, string> DisplayNames { get; set; }
```

"DataType" property

The data type of the "IContextDefinition" instance

```
HmiContextDataType DataType { get; set; }
```

The enumeration "HmiContextDataType" can contain the following values:

- Bool = 0x01
- SInt = 0x02

- Int = 0x03
- DInt = 0x04
- LInt = 0x05
- USInt = 0x06
- UInt = 0x07
- UDInt = 0x08
- ULInt = 0x09
- Real = 0x0A
- LReal = 0x0B
- LTime = 0x0C
- DateTime = 0x0D
- Byte = 0x11
- Word = 0x12
- DWord = 0x13
- LWord = 0x14
- String = 0x32

"Error" property

The error code of the "IContextDefinition" instance

Is set if the instance is read incorrectly.

```
UInt32 Error { get; }
```

ILoggedContext

Description

The C# interface "ILoggedContext" defines properties of context log entries of an "IContextDefinition" instance.

The context log entries are started and stopped using methods of the "IContextLogging" interface.

Members

"StartTime" property

The start time of the "IContextLogging" instance

```
DateTime StartTime { get; }
```

"EndTime" property

The end time of the "IContextLogging" instance

```
DateTime EndTime { get; }
```

"Error" property

The error code of the "IContextLogging" instance

```
UInt32 Error { get; }
```

"Value" property

The value of the "IContextLogging" instance

The value has the same data type as is specified by the "DataType" property of the "IContextDefinition" instance.

Example: An "IContextDefinition" instance has the name "Product" and the data type String. Its "IContextLogging" instance has the value "Limo".

```
object Value { get; }
```

"Quality" property

The QualityCode of the context value

```
UInt32 Quality { get; }
```

IContextError

Description

The C# interface "IContextError" specifies properties of error results that occur when generating ContextDefinitions in the database.

Members

"Name" property

Name of the "IContextDefintion" instance

```
string Name { get; }
```

"Error" property

The error code

```
UInt32 Error { get; }
```

IContextFilter

Description

The C# interface "IContextFilter" specifies the properties for filtering according to "ILoggedContext" instances.

Members

"Name" property

The name of the "IContextDefinition" instance for whose "ILoggedContext" instances filtering is performed.

```
string Name { set; get; }
```

"ProviderType" property

The HmiContextProviderType of an "IContextDefinition" instance for whose "ILoggedContext" instances the filtering is performed.

```
HmiContextProviderType ProviderType { set; get;}
```

The enumeration "HmiContextProviderType" can contain the following values:

- NoContext = 0
- Calendar = 1
  For "IContextDefinition" instances generated by the PI Option Calendar.
- PerformanceInsightMachineState = 2
  For "IContextDefinition" instances generated by the PI Option Performance Insight.
- LineCoordinator = 3
  For "IContextDefinition" instances generated by the PI Option Line Coordinator.
- UserDefined = 5
  It is a user-defined "IContextDefinition" instance, created by ODK, for example.

"Operator" property

The filter operator

```
string Operator { set; get; }
```

The operator is applied to the value. The following operators are allowed:

- For values with data type Int and Real:
  - =
  - !=
  - <
  - >
  - <=
  - >=
- For values with data type String:
  - LIKE
  - =

  Strings must always be fully specified.

```
string Operator { set; get; }
```

Examples of operators: ">", "<", ">=" , "<=" and "="

"Value" property

To filter by "Value" of the "ILoggedContext" instance

```
object Value { set; get; }
```

Example

Copying code

```
public void ReadContextWithFilter()
{
    Console.WriteLine("ReadContextWithFilter \n");
    var contextLogging = _runtime.GetObject<IContextLogging>();
    contextLogging.OnLoggedContextReadReply += OnLoggedContextReadReplyForContextLogging;
    IContextFilter Filter = _runtime.GetObject<IContextFilter>();
    if (Filter != null)
    {
     Filter.Name = "ContextName_" + strContext_Unique_Num;
     Filter.ProviderType = HmiContextProviderType.UserDefined;
     Filter.Operator = "=";
     Filter.Value = "Orange Juice";
    }
    contextLogging.ReadContexts(startDt, endDt, Filter, HmiSortingMode.Ascending);
    _event.WaitOne();
    _event.Reset();
    contextLogging.Dispose();
}
```

20.3.9 Description of the C++ interfaces

20.3.9.1 Error codes of the C++ interfaces

All methods that have defined a `CFRESULT` return `CFSUCCESS` if the method was run through successfully. Otherwise, they return a corresponding error code.

20.3.9.2 Interfaces of the Runtime environment

IOdkRt

Description

The C++ interface "IOdkRt" specifies methods for the connection to the Runtime system and the error handling.

Members

The following methods are specified in the interface:

"Connect" method

Checks whether valid licenses are available for the products installed on the Runtime device:

- Yes: Connects ODK application and Runtime project.
- No: Supplies an error code. Use the interfaces for error handling to query the error description (license missing, expired, etc.).

```
CFRESULT Connect(
         const CFSTR context,
         IRuntime **ppRuntime,
         const CTSTR user = nullptr,
         const CTSTR password = nullptr)
```

- `context`
  [in]: Name of the runtime project

  Note

  The name of the Runtime project is not used in the current version. An empty string must be passed in order to connect to the locally run Runtime project.

- `IRuntime`
  [out]: Points to the initialized "IRuntime" object that the ODK object model makes available.
- `user`
  [in]: User name

  Note

  Can only be used in a future version!

- `password`
  [in]: Password

  Note

  Can only be used in a future version!

"Close" method

Enable configuration files and plug-ins of the Runtime system.

```
CFRESULT Close()
```

"GetErrorHandler" method

Transfers an "IErrorInfo" object for error handling.

```
CFRESULT GetErrorHandler(IErrorInfo** pErrorInfo)
```

`IErrorInfo`
[out]: Points to an "IErrorInfo" object.

Example

Connect to the Runtime system of the active project:

Copy code

```
IRuntimePtr pRuntime;

CFRESULT Connect()
{
    // Connect to running project
    CCfString projectName = L"";
    CFRESULT retVal = Connect(projectName, &pRuntime);

    return retVal;
}
```

Error handling when reading out installed options of the Runtime system:

Copy code

```
void GetOptionObject(IRuntimePtr pRuntime)
{
    Siemens::Runtime::HmiUnified::Common::Cpp::IOptionPtr pOdkOption;
    //load option component by name
    pRuntime->GetOption(CCfString("MyOptionName"), &pOdkOption);

    ICfUnknownPtr pUnknown;
    //create a instance of the option object "MyOptionObject"
    pOdkOption->GetObject(CCfString("MyOptionObject"), &pUnknown);

    IMyOptionObjectPtr pMyOptionObject(pUnknown);
    CCfString strProperty;
    pMyOptionObject->GetMyProperty(&strProperty);
}
```

IRuntime (Page 7988)

IErrorInfo (Page 8001)

IRuntime

Description

The C++ interface "IRuntime" specifies methods for information and the addressing of the Runtime system.

Members

The following methods are specified in the interface:

"GetObject" method

Create new instance of an object of the Runtime system. Possible object types are defined in the configuration file OdkObjectModel.xml.

```
CFRESULT GetObject(const CFSTR value, ICfUnknown **ppObject)
```

- `value`
  [in]: Name of the object type, for example "Tag" for tags
- `ppObject`
  [out]: Points to the initialized object of the runtime system.

"GetProduct" method

Return an "IProduct" object that allows access to the version information and installed options of the Runtime system.

```
CFRESULT GetProduct(IProduct **ppProduct)
```

`ppProduct`
[in/out]: Points to an "IProduct" object that contains the product information of the runtime system.

"GetOption" method

Referencing installed option of the Runtime system.

```
CFRESULT GetOption(
         const CFSTR optionName,
         IOption **ppOption)
```

- `optionName`
  [in]: Name of the installed option
- `ppProduct`
  [out]: Points to an installed option of the Runtime system as "IOption" object.

"GetUserName" method

Return the name of the logged-on user.

```
CFRESULT GetUserName(CFSTR* name)
```

`name`
[out]: Displays the user name.

Example

Initialize an object of the "Tag" type of the Runtime system:

Copy code

```
CFRESULT ReadSingleTagSync(IRuntimePtr pRuntime, CCfString tag)
{
    ICfUnknownPtr pUnk;
    pRuntime->GetObject(CCfString(L"Tag"), &pUnk);

    ITagPtr pTag(pUnk);
    pTag->SetTagName(tag);
    ... //further tag processing
}
```

Output technical product version of the Runtime system:

Copy code

```
void GetVersionInfo(IRuntimePtr pRuntime)
{
   IProductPtr pProduct;
   pRuntime->GetProduct(&pProduct);

   uint16_t uintMajor, uintMinor, uintUpdate, uintServicePack;
   IVersionInfoPtr pVersion;

   pProduct->GetVersion(&pVersion);
   pVersion->GetMajor(&uintMajor);
   pVersion->GetMinor(&uintMinor);
   pVersion->GetServicePack(&uintServicePack);
   pVersion->GetUpdate(&uintUpdate);
   wcout << L"WinCC Unified version: " << uintMajor << L"-" << uintMinor << L"-" <<
uintServicePack << L"-" << uintUpdate << endl;
}
```

Use installed options:

Copy code

```
void GetOptionObject(IRuntimePtr pRuntime)
{
    Siemens::Runtime::HmiUnified::Common::Cpp::IOptionPtr pOdkOption;
    pRuntime->GetOption(CCfString("MyOptionName"), &pOdkOption);

    ICfUnknownPtr pUnk;
    pOdkOption->GetObject("MyOptionObject2", &pUnk);

    IMyOptionObjectPtr pMyOptionObject(pUnknown);
    CCfString strProperty;
    pMyOptionObject->GetMyProperty(&strProperty);

    //using extension methods for CPM node
    ICpmPtr pCpm;
    pRuntime->GetObject(CCfString("Cpm"), (ICfUnknown**) &pCpm);

    ICpmNodePtr pCpmNode;
    CCfString strNode(".hierarchy::PlantView\\Unit1");
    pCpm->GetNode(strNode, &pCpmNode);

    //using specific option interface
    IMyOptionPtr pMyOption(pOdkOption);

    IMyCpmNodeFormulaPtr pFormula;
    pMyOption->GetObject(pCpmNode, CCfString("Formula"), (ICfUnknown**) &pFormula);
    pFormula->SetName(CCfString("Quality"));
    int32_t result;
    pFormula->Calc(&result);
}
```

IProduct (Page 7991)

IOption (Page 7993)

IProduct

Description

The C++ interface "IProduct" specifies methods for handling product information of the Runtime system.

Members

The following methods are specified in the interface:

"GetOptions" method

Return installed options of the Runtime system as array of "IOption" objects.

```
CFRESULT GetOptions(IOptionEnumerator **ppEnumerator)
```

`ppEnumerator`
[out]: Points to the installed options as "IOptionEnumerator" object.

"GetVersion" method

Return version structure of the installed Runtime system as "IVersionInfo" object.

```
CFRESULT GetVersion(IVersionInfo** versionInfo)
```

`versionInfo`
[out]: Points to a structure with version information of the installed Runtime system.

Example

Output technical product version of the Runtime system:

Copy code

```
void GetVersionInfo(IRuntimePtr pRuntime)
{
   IProductPtr pProduct;
   pRuntime->GetProduct(&pProduct);
   uint16_t uintMajor, uintMinor, uintUpdate, uintServicePack;
   IVersionInfoPtr pVersion;

   pProduct->GetVersion(&pVersion);
   pVersion->GetMajor(&uintMajor);
   pVersion->GetMinor(&uintMinor);
   pVersion->GetServicePack(&uintServicePack);
   pVersion->GetUpdate(&uintUpdate);
   wcout << L"WinCC Unified version: " << uintMajor << L"-" << uintMinor << L"-" <<
uintServicePack << L"-" << uintUpdate << endl;
}
```

Output name of all installed options:

Copy code

```
void GetVersionInfo(IRuntimePtr pRuntime)
{
   IProductPtr pProduct;
   pRuntime->GetProduct(&pProduct);
   IOptionEnumeratorPtr pItems;

   while (pItems->MoveNext() == CF_SUCCESS)
   {
      IOptionPtr pValue;
      pItems->Current(&pValue);
      CCfString module;
      pValue->GetName(&module);
      wcout << L"Option name: " << module << endl;
   }
}
```

IOption (Page 7993)

IOptionEnumerator (Page 7994)

IVersionInfo (Page 7996)

IOption

Description

The C++ interface "IOption" specifies properties and methods for handling installed product options of the Runtime system.

Members

The following methods are specified in the interface:

"GetName" method

Return name of an installed option of the Runtime system.

```
CFRESULT GetName(CFSTR *pValue)
```

`pValue`
[out]: Points to the name of an installed option of the runtime system.

"GetObject" method

Referencing installed option of the Runtime system.

```
CFRESULT GetObject(
         const CFSTR Value,
         ICfUnknown** ppObject)
```

- `Value`
  [in]: Name of the installed option of the Runtime system
- `ppObject`
  [out]: Points to the installed option of the Runtime system as an "ICfUnknown" object.

"GetVersion" method

Reference version structure of an installed option of the Runtime system as "IVersionInfo" object.

```
CFRESULT GetVersion(IVersionInfo** versionInfo)
```

`versionInfo`
[out]: Points to a structure with version information of an installed option of the Runtime system.

Example

Read out installed option:

Copy code

```
void GetOptionObject(IRuntimePtr pRuntime)
{
    Siemens::Runtime::HmiUnified::Common::Cpp::IOptionPtr pOdkOption;
    pRuntime->GetOption(CCfString("MyOptionName"), &pOdkOption);

    ICfUnknownPtr pUnk;
    pOdkOption->GetObject("MyOptionObject2", &pUnk);

    IMyOptionObjectPtr pMyOptionObject(pUnknown);
    CCfString strProperty;
    pMyOptionObject->GetMyProperty(&strProperty);
}
```

IOptionEnumerator (Page 7994)

IVersionInfo (Page 7996)

IOptionEnumerator

Description

The "IOptionEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of installed product options of the Runtime system.

All the methods return CF_SUCCESS in case of successful execution.

Members

The following methods are specified in the interface:

"Current" method

Output the current element of the enumeration of a list.

```
CFRESULT Current(IOption **ppItem)
```

ppItem
[out]: Points to the current "IOption" object as an element of the list.

"MoveNext" method

Go to the next element of the enumeration of a list.

```
CFRESULT MoveNext()
```

"Reset" method

Reset the current position in the enumeration of a list.

```
CFRESULT Reset()
```

The "MoveNext"method subsequently moves to the first element of the list.

"Count" method

Output the size of the enumeration or the number of elements of a list.

```
CFRESULT Count(uint32_t *value)
```

value
[out]: Points to the value for the number of the elements of the list.

Example

Access the installed options "IOption" of the runtime system:

Copy code

```
void GetVersionInfo(IRuntimePtr pRuntime)
{
   IProductPtr pProduct;
   pRuntime->GetProduct(&pProduct);

   pProduct->GetOptions(&pItems);
   IOptionEnumeratorPtr pItems;

   while (pItems->MoveNext() == CF_SUCCESS)
   {
      IOptionPtr pValue;
      pItems->Current(&pValue);
      ...
   }
}
```

IOption (Page 7993)

IVersionInfo

Description

The C++ interface "IVersionInfo" specifies methods for reading out version information of the runtime system.

Members

The following methods are specified in the interface:

"GetMajor" method

Return main version of an installed option of the Runtime system.

```
CFRESULT GetMajor(uint16_t *pValue)
```

`pValue`
[out]: Points to the main version of an installed option of the Runtime system.

"GetMinor" method

Return minor version of an installed option of the Runtime system.

```
CFRESULT GetMinor(uint16_t *pValue)
```

`pValue`
[out]: Points to the minor version of an installed option of the Runtime system.

"GetServicePack" method

Return service pack of an installed option of the Runtime system.

```
CFRESULT GetServicePack(uint16_t *pValue)
```

`pValue`
[out]: Points to the service pack of an installed option of the Runtime system.

"GetUpdate" method

Return update version of an installed option of the Runtime system.

```
CFRESULT GetUpdate(uint16_t *pValue)
```

`pValue`
[out]: Points to the update version of an installed option of the Runtime system.

Example

Output technical product version of the Runtime system:

Copy code

```
void GetVersionInfo(IRuntimePtr pRuntime)
{
   IProductPtr pProduct;
   pRuntime->GetProduct(&pProduct);

   uint16_t uintMajor, uintMinor, uintUpdate, uintServicePack;
   IVersionInfoPtr pVersion;

   pProduct->GetVersion(&pVersion);
   pVersion->GetMajor(&uintMajor);
   pVersion->GetMinor(&uintMinor);
   pVersion->GetServicePack(&uintServicePack);
   pVersion->GetUpdate(&uintUpdate);
   wcout << L"WinCC Unified version: " << uintMajor << L"-" << uintMinor << L"-" <<
uintServicePack << L"-" << uintUpdate << endl;
}
```

IProduct (Page 7991)

IOption (Page 7993)

IErrorResult

Description

The "IErrorResult" interface is a C++ interface that specifies methods for reading out error details.

Members

The following methods are specified in the interface:

"GetError" method

Read out error code of an error message.

```
CFRESULT GetError(CFRESULT *value)
```

`value`
[out]: Points to an error code.

"GetName" method

Read out name of the associated object of the data source.

```
CFRESULT GetError(CFSTR *value)
```

`value`
[out]: Points to an object name.

Example

Read out details of "IErrorResult" error messages:

Copy code

```
IErrorResultEnumerator* WriteTagSetSync(IRuntimePtr pRuntime, std::vector<TagTuple_T> tags)
{
    ICfUnknownPtr pUnk;
    CFRESULT errCode = pRuntime->GetObject(CCfString(L"TagSet"), &pUnk);
    IErrorResultEnumerator* pEnumerator = nullptr;

    ITagSetPtr pTagSet(pUnk);

    // add tags to tag set
    for (int i = 0; i < tags.size(); i++)
    {
       pTagSet->AddWithValue(CCfString(tags[i]._tagName), tags[i]._tagValue);
    }

    errCode = pTagSet->Write(&pEnumerator);
    if (CF_FAILED(errCode))
    {
       std::wcout << L"Write operation failed." << std::endl;
       PrintErrorInformation(errCode, L"Write", pRuntime);
    }
    if (pEnumerator != nullptr)
    {
       while (pEnumerator->MoveNext() == CF_SUCCESS)
       {
          IErrorResult* pValue;
          CFRESULT errorCode = pEnumerator->Current(&pValue);
          if (pValue != nullptr && CF_SUCCEEDED(errorCode))
          {
             pValue->GetError(&errorCode);
             CCfString str;
             pValue->GetName(&str);
             if (CF_FAILED(errorCode))
             {
                std::wcout << L"Write Tag failed, Tag name: " << str << L", ErrorCode:" <<
errorCode << std::endl;
                PrintErrorInformation(errorCode, L"Write Tag", pRuntime);
             }
          }
       }
    }
    return pEnumerator;
}
```

IErrorResultEnumerator (Page 7999)

IErrorResultEnumerator

Description

The "IErrorResultEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of error messages of the Runtime system.

All the methods return CF_SUCCESS following successful execution.

Members

The following methods are specified in the interface:

"Current" method

Output the current element of the enumeration of a list.

```
CFRESULT Current(IErrorResult **ppItem)
```

`ppItem`
[out]: Points to the current "IErrorResult" object as an element of the list.

"MoveNext" method

Go to the next element of the enumeration of a list.

```
CFRESULT MoveNext()
```

"Reset" method

Reset the current position in the enumeration of a list.

```
CFRESULT Reset()
```

The "MoveNext" method moves afterwards to the first element of the list.

"Count" method

Output the size of the enumeration or the number of elements of a list.

```
CFRESULT Count(uint32_t *value)
```

`value`
[out]: Points to the value for the number of elements of the list.

Example

Access the "IErrorResult" error messages when writing a TagSet:

Copy code

```
IErrorResultEnumerator* WriteTagSetSync(IRuntimePtr pRuntime, std::vector<TagTuple_T> tags)
{
    ICfUnknownPtr pUnk;
    CFRESULT errCode = pRuntime->GetObject(CCfString(L"TagSet"), &pUnk);
    IErrorResultEnumerator* pEnumerator = nullptr;

    ITagSetPtr pTagSet(pUnk);

    // add tags to tag set
    for (int i = 0; i < tags.size(); i++)
    {
       pTagSet->AddWithValue(CCfString(tags[i]._tagName), tags[i]._tagValue);
    }

    errCode = pTagSet->Write(&pEnumerator);
    if (CF_FAILED(errCode))
    {
       std::wcout << L"Write operation failed." << std::endl;
       PrintErrorInformation(errCode, L"Write", pRuntime);
    }
    if (pEnumerator != nullptr)
    {
       while (pEnumerator->MoveNext() == CF_SUCCESS)
       {
          IErrorResult* pValue;
          CFRESULT errorCode = pEnumerator->Current(&pValue);
          if (pValue != nullptr && CF_SUCCEEDED(errorCode))
          {
             pValue->GetError(&errorCode);
             CCfString str;
             pValue->GetName(&str);
             if (CF_FAILED(errorCode))
             {
                std::wcout << L"Write Tag failed, Tag name: " << str << L", ErrorCode:" <<
errorCode << std::endl;
                PrintErrorInformation(errorCode, L"Write Tag", pRuntime);
             }
          }
       }
    }
    return pEnumerator;
}
```

ITagSet (Page 8014)

ITagSetQCD (Page 8019)

IErrorInfo

Description

The "IErrorInfo" interface is a C++ interface that specifies methods for handling error codes.

Members

The following methods are specified in the interface:

"GetErrorDescription" method

Output an error description for the error code.

You have to use the "GetErrorHandler" method to instantiate an "IErrorInfo" object beforehand.

```
CFRESULT GetErrorDescription(
         uint32_t errorCode,
         CFSTR *errorDescription)
```

- `errorCode`
  [in]: Error code that is handed over by the ODK client.
- `errorDescription`
  [out]: Points to the error description of the error code.

Example

Output object name and description of an error:

Copy code

```
void PrintErrorInformation(CFRESULT errorCode, CCfSmartString objectName, IRuntimePtr
pRuntime)
{
   if (pRuntime != nullptr)
   {
      IErrorInfoPtr pInfo;
      CFRESULT result = pRuntime->GetObject(CCfString(L"ErrorHandler"),
(ICfUnknown**)&pInfo);
      if (CF_FAILED(result))
      {
         std::wcout << "Error occurred: Can not create 'ErrorHandler' object " << std::endl;
         return;
      }
      CCfString resStr;
      result = pInfo->GetErrorDescription(errorCode, &resStr);
      if (CF_SUCCEEDED(result))
      {
         CCfSmartString errorDescription(resStr);
         std::wcout << "Error occurred: '" << errorDescription.Get() << "', ObjectName = "
<< objectName.Get() << std::endl;
      }
      else
      {
         std::wcout << "Error occurred: 'GetErrorDescription' failed, Error number: " <<
result << std::endl;
      }
   }
   else
   {
      CCfString strMsg(L"");
      Siemens::Runtime::HmiUnified::Common::IErrorInfo* pErrorInfo;
      GetErrorHandler(&pErrorInfo);
      CFRESULT rVal = pErrorInfo->GetErrorDescription(errorCode, &strMsg);
      CCfSmartString errorDescription(strMsg);
      std::wcout << "Error occurred: '" << errorDescription.Get() << "', ObjectName = " <<
objectName.Get() << std::endl;
   }
}
```

20.3.9.3 Interfaces of the tags

IProcessValue

Description

The C++ interface "IProcessValue" specifies properties and methods for values of process tags of the Runtime system. The "IProcessValue" interface represents values from the result of a read operation or monitoring.

Members

The following methods are specified in the interface:

"GetTagName" method

Return the name of the tag.

```
CFRESULT GetTagName(CFSTR *value)
```

`value`
[out]: Points to the name of the tag belonging to the process value.

"GetValue" method

Return value of the tag at the moment of the read operation.

```
CFRESULT GetValue(CFVARIANT *value)
```

`value`
[out]: Points to the process value of the tag.

"GetQuality" method

Return quality code of the read operation of the tag.

```
CFRESULT GetQuality(int32_t *value)
```

`value`
[out]: Points to the quality code of the process tag.

"GetTimeStamp" method

Return the time stamp of the last successful read operation of the tag.

```
CFRESULT GetTimeStamp(CFDATETIME64 *value)
```

`value`
[out]: Points to the time stamp of the read operation of the process tag.

"GetError" method

Return error code of the last read or write operation of the tag.

```
CFRESULT GetError(int32_t *value)
```

`value`
[out]: Points to the error code of the process tag.

Example

Read out a process tag and output the properties of the "IProcessValue" object:

Copy code

```
CFRESULT ReadSingleTagSync(IRuntimePtr pRuntime, CCfString tag)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"Tag"), &pUnk);

   ITagPtr pTag(pUnk);
   pTag->SetTagName(tag);
   IProcessValuePtr pValue;

   // Read value of tag
   pTag->Read(&pValue);

   CCfString timeStamp;
   CFDATETIME64 cfTimeStamp;
   pValue->GetTimeStamp(&cfTimeStamp);
   CCfDateTime64 time(cfTimeStamp);
   timeStamp = time.GetDateTimeString(false);
   CCfString strName;
   pValue->GetTagName(&strName);
   CCfVariant varValue;
   pValue->GetValue(&varValue);
   int32_t quality;
   pValue->GetQuality(&quality);

   std::wcout << strName.ToUTF8().c_str() << L" " << timeStamp.ToUTF8().c_str() << L" " <<
L" Value: " << (double)(varValue) << L" Quality: " << quality << std::endl;
}
```

IProcessValueEnumerator (Page 8004)

ITag (Page 8006)

ITagSet (Page 8014)

ITagSetQCD (Page 8019)

IProcessValueEnumerator

Description

The "IProcessValueEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of process values of the Runtime system. The enumeration is, for example, used when reading out process values of a TagSet.

All the methods return CF_SUCCESS in case of successful execution.

Members

The following methods are specified in the interface:

"Current" method

Output the current element of the enumeration of a list.

```
CFRESULT Current(IProcessValue **ppItem)
```

`ppItem`
[out]: Points to the current "IProcessValue" object as an element of the list.

"MoveNext" method

Go to the next element of the enumeration of a list.

```
CFRESULT MoveNext()
```

"Reset" method

Reset the current position in the enumeration of a list.

```
CFRESULT Reset()
```

The "MoveNext"method subsequently moves to the first element of the list.

"Count" method

Output the size of the enumeration or the number of elements of a list.

```
CFRESULT Count(uint32_t *value)
```

`value`
[out]: Points to the value for the number of the elements of the list.

Example

Output process values of TagSets:

Copy code

```
...
IProcessValueEnumeratorPtr pItems;
pTagSet->Read(&pItems);

std::wcout << "Read finished " << std::endl;
// Iterate over the process value objects
while(CF_SUCCEEDED(pItems->MoveNext()))
{
   IProcessValuePtr pValue;
   pItems->Current(&pValue);   // get current process value

   CCfString timeStamp;
   CFDATETIME64 cfTimeStamp;
   pValue->GetTimeStamp(&cfTimeStamp);
   CCfDateTime64 time(cfTimeStamp);
   timeStamp = time.GetDateTimeString(false);
   CCfString strName;

   pValue->GetTagName(&strName);
   CCfVariant varValue;
   pValue->GetValue(&varValue);
   int32_t quality;
   pValue->GetQuality(&quality);
   int32_t error = 0;
   pValue->GetError(&error);
   std::wcout << L" " << strName.ToUTF8().c_str() << L" " << timeStamp.ToUTF8().c_str() <<
L" " << L" Value: " << static_cast<double>(varValue) << L" Quality: " << quality << L"
Error: " << (uint32_t)error << std::endl;
}
...
```

See also

IProcessValue (Page 8003)

ITag

Description

The C++ interface "ITag" specifies methods for handling tags of the Runtime system.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

The following methods are specified in the interface:

"SetTagName" method

Set name of the tag.

```
CFRESULT SetTagName(const CFSTR tagName)
```

`tagName`
[in]: Name of the tag

"Write" method

Write process value of the tag synchronously in the Runtime system.

```
CFRESULT Write(
         const CFVARIANT value,
         CFENUM type = HmiWriteType::NoWait)
```

- `value`
  [in]: Tag value
- `type`
  [in/optional]: The enumeration "HmiWriteType" specifies whether the method waits for the write operation to be completed:
  - `HmiWriteType::NoWait` (default): Writes the tag value without waiting. Errors for the write operation are not detected.
  - `HmiWriteType::Wait`: Waits until the tag value is written in the AS. The associated errors are written.

"WriteQCD" method

Write process value with quality code of the tag synchronously in the Runtime system. The tag also has a freely definable time stamp. You can use this to acquire past external measured values, for example.

Note

Reaction to external tags

For external tags, the method only writes the tag value. The QualityCode and time stamp are set internally by the system.

```
CFRESULT WriteQCD(
         const CFVARIANT value,
         const CFDATETIME64 timeStamp,
         const int16_t qualityCode,
         CFENUM type = HmiWriteType::NoWait)
```

- `value`
  [in]: Tag value
- `timeStamp`
  [in]: Time stamp of the tag. Also in the past.

- `qualityCode`
  [in]: Quality code of the tag
- `type`
  [in/optional]: The enumeration "HmiWriteType" specifies whether the method waits for the write operation to be completed:
  - `HmiWriteType::NoWait` (default): Writes the tag value without waiting. Errors for the write operation are not detected.
  - `HmiWriteType::Wait`: Waits until the tag value is written in the AS. The associated errors are written.

"WriteWithOperatorMessage" method

Write process value of the tag synchronously in the runtime system and create operator input alarm. In addition to the reason, the operator input alarm contains the old and new value, the user and host names and the unit.

```
CFRESULT WriteWithOperatorMessage(
         const CFVARIANT value,
         const CFSTR reason)
```

- `value`
  [in]: Value of the tag
- `reason`
  [in]: Reason for the value change for alarm

"Read" method

Read process value and properties of the tag synchronously from the Runtime system.

```
CFRESULT Read(
         IProcessValue **ppValue,
         CFENUM type = HmiReadType::Cache)
```

- `ppValue`
  [out]: Points to the properties and the value of the tag as an "IProcessValue" object.
- `type`
  [in/optional]: The enumeration "HmiReadType" specifies the origin of the tag value:
  - `HmiReadType::Cache` (default): Reads the tag value from the tag image. If no subscription exists, the tag is subscribed.
  - `HmiReadType::Device`: Reads the tag value directly from the AS. The tag image is not used.

Example

Write tags synchronously:

Copy code

```
CFRESULT WriteSingleTagSync(IRuntimePtr pRuntime, CCfString tag, CCfVariant& value)
{
   ICfUnknownPtr pUnk;
   CFRESULT errCode = pRuntime->GetObject(CCfString(L"Tag"), &pUnk);
   ITagPtr pTag(pUnk);
   pTag->SetTagName(tag);
   // Write value of tag
   errCode = pTag->Write(value, HmiWriteType::Wait);
   return errCode;
}
```

Write tag with time stamp and quality code synchronously:

Copy code

```
void WriteSingleTagQCDSync(IRuntimePtr pRuntime, CCfString tag, CCfVariant& value)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"Tag"), &pUnk);
   ITagPtr pTag(pUnk);
   pTag->SetTagName(tag);
   // Write value of tag
   pTag->WriteQCD(value, CCfDateTime64::Now(), 128, HmiWriteType::Wait);
}
```

Read tags synchronously:

Copy code

```
CFRESULT ReadSingleTagSync(IRuntimePtr pRuntime, CCfString tag)
{
    ICfUnknownPtr pUnk;
    pRuntime->GetObject(CCfString(L"Tag"), &pUnk);

    ITagPtr pTag(pUnk);
    pTag->SetTagName(tag);

    IProcessValuePtr pValue;

    // Read value of tag
    pTag->Read(&pValue);
    ...

    return errCode;
}
```

See also

IProcessValue (Page 8003)

ITagCallback (Page 8010)

ITagCallback

Description

The "ITagCallback" interface and the "COdkTagSourceCBBase" and "COdkTagSetCB" classes define methods for implementing asynchronous read and write operations with tags. The methods are used by the C++-interface "ITagSet".

Members of the interface

The following methods are specified in the "ITagCallback" interface:

"OnReadComplete" method

Callback method is called on completion of asynchronous read operations.

The "OnReadComplete" callback method is called when the "ITagSet.ReadAsync" method is used.

```
CFRESULT OnReadComplete(
         IProcessValueEnumerator *pEnumerator,
         uint32_t errorCode,
         int32_t contextId,
         CFBOOL completed)
```

- `pEnumerator`
  [out]: Points to an "IProcessValueEnumerator" object that contains the enumeration of the read process values.
- `systemError`
  [out]: Error code for the asynchronous operation
- `contextId`
  [out]: ContextID as additional identification feature of the tag.
- `completed`
  [out]: Status of the asynchronous transfer:
  - True: All alarms are read out.
  - False: Not all alarms are read out yet.

"OnWriteComplete" method

Callback method is called on completion of asynchronous write operations.

The "OnWriteComplete" callback method is called when the "ITagSet.WriteAsync" method is used.

```
CFRESULT OnWriteComplete(
         IErrorResultEnumerator *pEnumerator,
         uint32_t errorCode,
```

```
        int32_t contextId
        CFBOOL completed)
```

- `pEnumerator`
  [out]: Points to an "IErrorResultEnumerator" object that contains the enumeration with errors for the write operations of the tag.
- `systemError`
  [out]: Error code for the asynchronous operation
- `contextId`
  [out]: ContextID as additional identification feature of the tag.
- `completed`
  [out]: Status of the asynchronous transfer:
  - True: All alarms are read out.
  - False: Not all alarms are read out yet.

"OnDataChanged" method

Callback method is called when a monitored tag value is changed.

The callback method is called after the process value change of a monitored TagSet ("ITagSet.Subscribe" method).

```
CFRESULT OnDataChanged(
        IProcessValueEnumerator *pEnumerator,
        uint32_t errorCode,
        int32_t contextId)
```

- `pEnumerator`
  [out]: Points to an "IProcessValueEnumerator" object that contains the enumeration of the read process values.
- `systemError`
  [out]: Error code for the asynchronous operation
- `contextId`
  [out]: ContextID as additional identification feature of the tag.

Members of the classes

The following methods are implemented in the "COdkTagSourceCBBase" and "COdkTagSetCB" classes:

"SetEvent" method

Signals an event.

```
CFBOOL SetEvent()
```

"ResetEvent" method

Resets the signaling of an event.

```
CFBOOL ResetEvent()
```

"WaitForcompletion" method

Waits for the signaling of an event.

```
uint32_t WaitForcompletion(uint32_t dwMilliseconds)
```

`dwMilliseconds`
[in]: Time interval in milliseconds for which an event is waited for.

"GetValues" method

Return process values of the asynchronous read operation.

```
std::vector<IProcessValue*> GetValues()
```

Example

In the following section tags in a TagSet are read asynchronously. To this purpose the "ReadTagSetAsync" function uses a "COdkTagSetCB" object that implements the "ITagCallback" interface and that uses the "COdkTagSourceCBBase" class. The service life of the "COdkTagSetCB" object is determined via reference counting.

Copy code

```
void ReadTagSetAsync(IRuntimePtr pRuntime, std::vector<CCfString> tags)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"TagSet"), &pUnk);
   ITagSetPtr pTagSet(pUnk);
   // add tags to tag set
   for(int i = 0; i < tags.size(); i++)
   {
      pTagSet->Add(tags[i]);
   }

   COdkTagSetCB* pTagSetCB = new COdkTagSetCB();
   pTagSetCB->AddRef();
   // Read the tag set asynchronously, result comes via callback
   pTagSet->ReadAsync(pTagSetCB);
   pTagSetCB->WaitForcompletion(std::numeric_limits<uint32_t>::max();
   vector<IProcessValuePtr> pValues = pTagSetCB->GetValues();
   std::wcout << L"Read finished " << std::endl;

    // display tag values
   for(int i = 0; i < pValues.size(); i++)
   {
      IProcessValue* pValue = pValues[i];
      CCfString timeStamp;
      CFDATETIME64 cfTimeStamp;
      pValue->GetTimeStamp(&cfTimeStamp);
      CCfDateTime64 time(cfTimeStamp);
      timeStamp = time.GetDateTimeString(false);
      CCfString strName;
      pValue->GetTagName(&strName);
      CCfVariant varValue;
      pValue->GetValue(&varValue);
      int32_t quality;
      pValue->GetQuality(&quality);
      int32_t error = 0;
      pValue->GetError(&error);
      std::wcout << L" " << strName.ToUTF8().c_str() << L" " << timeStamp.ToUTF8().c_str()
<< L" " << L" Value: " << static_cast<double>(varValue) << L" Quality: " << quality << L"
Error: " << (uint32_t)error << std::endl;
   }
}
```

ITag (Page 8006)

ITagSet (Page 8014)

ITagSetQCD (Page 8019)

ITagSet

Description

The C++ interface "ITagSet" specifies properties and methods for an optimized access to several tags of the Runtime system.

After initialization of the "ITagSet" object, you can execute read and write access to multiple tags in one call. Simultaneous access demonstrates better performance and lower communication load than single access to multiple tags.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

The following methods are specified in the interface:

"SetContextId" method

Set ID as an additional identification feature of the tag. The ContextId can, for example, be used to recognize identically named tags from different monitoring functions. Default value -1: The ContextId is not used.

```
CFRESULT SetContextId(const int32_t value)
```

`value`
[in]: ContextId of the tag:

"GetContextId" method

Set ID as an additional identification feature of the tag. The ContextId can, for example, be used to recognize identically named tags from different monitoring functions. Default value -1: The ContextId is not used.

```
CFRESULT GetContextId(int32_t *value)
```

`value`
[out]: Points to the ContextId of the tag.

"Remove" method

Remove individual tag from a TagSet.

```
CFRESULT Remove(const CFSTR tagName)
```

`tagName`
[in]: Name of the tag that is removed from TagSet.

"Add" method

Add tag to a TagSet.

```
CFRESULT Add(const CFSTR tagName)
```

`tagName`
[in]: Name of the tag for TagSet

"AddWithValue" method

Add tag with process value to the TagSet.

```
CFRESULT AddWithValue(const CFSTR tagName, const CFVARIANT value)
```

- `tagName`
  [in]: Name of the tag
- `value`
  [in]: New value of the tag

"GetValue" method

Read process value of a tag of a TagSet.
To fill the local TagSet with process values, a "Read", "ReadAsync" or "AddWithValue" method must be called beforehand.

The values of the "IProcessValue" object are not available until after execution of the methods "Read", "ReadAsync" or "AddWithValue".

```
CFRESULT GetValue(const CFSTR tagName, CFVARIANT *pValue)
```

- `tagName`
  [in]: Name of the tag from the TagSet
- `pValue`
  [out]: Points to the process value of the tag.

"SetValue" method

Change the process value of a tag of a TagSet.

The "SetValue" method changes only the values of the local TagSet. In order to write the changed values into the automation system you must additionally execute the "Write" or "WriteAsync" method.

```
CFRESULT SetValue(const CFSTR tagName, const CFVARIANT value)
```

- `tagName`
  [in]: Name of the tag from the TagSet
- `value`
  [in]: New value of the tag

"Write" method

Write process values of all tags of a TagSet synchronously in the Runtime system.

```
CFRESULT Write(HmiUnified::Rt::IErrorResultEnumerator
**ppEnumerator, CFENUM type = HmiWriteType::NoWait)
```

- `ppEnumerator`
  [out]: Points to an "IErrorResultEnumerator" object that contains the enumeration with errors for the write operations.
- `type`
  [in/optional]: The enumeration "HmiWriteType" specifies whether the method waits for the write operation to be completed:
  - `NoWait` (default): Writes the tag values without waiting. Errors for the write operation are not detected.
  - `Wait`: Waits until the tag values are written in the automation system. The associated errors are written.

"WriteWithOperatorMessage" method

Write process values of all tags of a TagSet synchronously in the Runtime system and create operator input alarms. In addition to the reason, the operator input alarms contain the old and new value, the user and host names and the unit.

```
CFRESULT WriteWithOperatorMessage(const CFSTR reason)
```

`reason`
[in]: Reason for the value change for alarm

"WriteAsync" method

Write process values of all tags of a TagSet asynchronously in the Runtime system.

The method always has the `HmiWriteType::Wait` type and waits until the tag value has been written in the automation system. Associated errors are written.

```
CFRESULT WriteAsync(
         ITagCallback* pTagSetCb)
```

- `pTagSetCb`
  [in]: Points to the "ITagCallback" object that implements the callback interface.

"Read" method

Read process values and properties of all the tags of a TagSet synchronously from the Runtime system.

```
CFRESULT Read(
         IProcessValueEnumerator **ppEnumerator,
         CFENUM type = HmiReadType::Cache)
```

- `ppEnumerator`
  [in/out]: Points to the properties and process values of the tags as an "IProcessValueEnumerator" object.
- `type`
  [in/optional]: The enumeration "HmiReadType" specifies the origin of the tag value:
  - `Cache` (default): Reads the tag values from the tag image. If no subscription exists, the tag is subscribed.
  - `Device`: Reads the tag values directly from the automation system. The tag image is not used.

"ReadAsync" method

Read process values and properties of all the tags of a TagSet asynchronously from the Runtime system.

```
CFRESULT ReadAsync(
         ITagCallback *pTagSetCb,
         CFENUM type = HmiReadType::Cache)
```

- `pTagSetCb`
  [in]: Points to the "ITagCallback" object that implements the callback interface.
- `type`
  [in/optional]: The enumeration "HmiReadType" specifies the origin of the tag value:
  - `Cache` (default): Reads the tag value from the tag image. If no subscription exists, the tag is subscribed.
  - `Device`: Reads the tag value directly from the AS. The tag image is not used.

"Subscribe" method

Subscribe all tags of a TagSet asynchronously for cyclic monitoring of the process values.

Note

Tags from IO devices with the "Cyclic in operation" acquisition mode

For a tag with the acquisition mode "Cyclic in operation", the value stored in the process image when Subscribe is called might be outdated. OnAdd therefore only provides the QualityCode "uncertain". Only value changes made after the Subscribe call provide the current value and the QualityCode "good".

```
CFRESULT Subscribe(ITagCallback *pTagSetCb)
```

`pTagCb`
[in]: Points to the "ITagCallback" object that implements the callback interface.

"CancelSubscribe" method

Cancel monitoring of all tags of a TagSet.

```
CFRESULT CancelSubscribe()
```

"GetCount" method

Return the number of tags of a TagSet list.

```
CFRESULT GetCount(int32_t *value)
```

`value`
[out]: Points to the value for the number of tags of the TagSet list.

"Clear" method

Remove all tags from a TagSet.

```
CFRESULT Clear()
```

Example

Write TagSet asynchronously:

Copy code

```
struct TagTuple_T
{
    CCfSmartString _tagName;
    CCfVariant _tagValue;
};

void WriteTagSetAsync(IRuntimePtr pRuntime, std::vector<TagTuple_T> tags)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"TagSet"), &pUnk);
   vector<IErrorResultPtr> pErrors;
   ITagSetPtr pTagSet(pUnk);

   // add tags to tag set
   for(int i = 0; i < tags.size(); i++)
   {
      pTagSet->AddWithValue(CCfString(tags[i]._tagName), tags[i]._tagValue);
   }

   COdkTagSetCB* pTagSetCB = new COdkTagSetCB();
   pTagSetCB->AddRef();
   // Write value of tag asynchronously
   pTagSet->WriteAsync(pTagSetCB);
   pTagSetCB->WaitForcompletion(std::numeric_limits<uint32_t>::max());
}
```

Start monitoring for tags of a TagSet:

Copy code

```
void SubscribeTagSet(IRuntimePtr pRuntime, std::vector<CCfString> tags)
{
   ICfUnknown* pUnk;
   pRuntime->GetObject(CCfString(L"TagSet"), &pUnk);
   ITagSetPtr pTagSet(pUnk);
   // add tags to tag set
   for(int i = 0; i < tags.size(); i++)
   {
      pTagSet->Add(tags[i]);
   }
   COdkTagSetCB* pTagSetCB = new COdkTagSetCB();
   pTagSetCB->AddRef();
   // subscribe tags
   pTagSet->Subscribe(pTagSetCB);
   pTagSetCB->WaitForcompletion(1500);
   std::wcout << L"Stop subscribtion." << std::endl;
   pTagSet->CancelSubscribe();
}
```

IProcessValue (Page 8003)

ITagCallback (Page 8010)

IErrorResultEnumerator (Page 7999)

ITagSetQCD

Description

The C++ interface "ITagSetQCD" specifies methods for optimized writing of several tags of the Runtime system. The tags also have a freely definable time stamp and quality code. You can use this to acquire past external measured values, for example.

Note

Reaction to external tags

For external tags, the method only writes the tag value. The QualityCode and time stamp are set internally by the system.

After initialization of the "ITagSetQCD" object, you can have read access to multiple tags in one call. Simultaneous access demonstrates better performance and lower communication load than single access to multiple tags.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

The following methods are specified in the interface:

"SetContextId" method

Set ID as an additional identification feature of the tag. The ContextId can, for example, be used to recognize identically named tags from different monitoring functions. Default value -1: The ContextId is not used.

```
CFRESULT SetContextId(const int32_t value)
```

`value`
[in]: ContextId of the tag:

"GetContextId" method

Set ID as an additional identification feature of the tag. The ContextId can, for example, be used to recognize identically named tags from different monitoring functions. Default value -1: The ContextId is not used.

```
CFRESULT GetContextId(int32_t *value)
```

`value`
[out]: Points to the ContextId of the tag.

"Remove" method

Remove individual tag from a TagSet.

```
CFRESULT Remove(const CFSTR tagName)
```

`tagName`
[in]: Name of the tag that is removed from TagSet.

"Add" method

Add tag with process value, quality code and time stamp to the TagSet.

```
CFRESULT Add(
         const CFSTR tagName,
         const CFVARIANT value,
         const CFDATETIME64 timeStamp,
         const int16_t qualityCode)
```

- `tagName`
  [in]: Name of the tag for TagSet
- `value`
  [in]: New process value of the tag
- `timeStamp`
  [in]: Time stamp of the process value. Also in the past.
- `qualityCode`
  [in]: Quality code for process value

"Write" method

Write process values of all tags of a TagSet synchronously in the Runtime system.

```
CFRESULT Write(HmiUnified::Rt::IErrorResultEnumerator
**ppEnumerator, CFENUM type = HmiWriteType::NoWait)
```

- `ppEnumerator`
  [out]: Points to an "IErrorResultEnumerator" object that contains the enumeration with errors for the write operations.
- `type`
  [in/optional]: The enumeration "HmiWriteType" specifies whether the method waits for the write operation to be completed:
  - `HmiWriteType::NoWait` (default): Writes the tag values without waiting. Errors for the write operation are not detected.
  - `HmiWriteType::Wait`: Waits until the tag values are written in the automation system. The associated errors are written.

"WriteAsync" method

Write process values of all tags of a TagSet asynchronously in the Runtime system.

The method always has the `HmiWriteType::Wait` type and waits until the tag value has been written in the automation system. Associated errors are written.

```
CFRESULT WriteAsync(
         ITagCallback* pTagSetCb)
```

- `pTagSetCb`
  [in]: Points to the "ITagCallback" object that implements the callback interface.

"GetCount" method

Return the number of tags of a TagSet list.

```
CFRESULT GetCount(int32_t *value)
```

`value`
[out]: Points to the value for the number of tags of the TagSet list.

"GetItem" method

Return tag of the TagSet for changing or reading out process value, QualityCode and time stamp.

```
CFRESULT GetItem(
         const CFSTR name,
         ITagSetQCDItem **pTagSetQCDItem)
```

- `name`
  [in]: Name of the tag in the TagSet
- `pTagSetQCDItem`
  [out]: Points to tag as "TagSetQCDItem" object

"Clear" method

Remove all tags from a TagSet.

```
CFRESULT Clear()
```

Example

Write TagSet with time stamp and quality code synchronously:

Copy code

```
struct TagTuple_T
{
    CCfSmartString _tagName;
    CCfVariant _tagValue;
};

void WriteTagSetQCDSync(IRuntimePtr pRuntime, std::vector<TagTuple_T> tags)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"TagSetQCD"), &pUnk);
   ITagSetQCDPtr pTagSetQCD(pUnk);

   // add tags to tag set
   for(int i = 0; i < tags.size(); i++)
   {
     pTagSetQCD->Add(CCfString(tags[i]._tagName), tags[i]._tagValue, CCfDateTime64::Now(),
128);
   }
   IErrorResultEnumerator* pEnumerator;
   pTagSetQCD->Write(&pEnumerator);
   while (pEnumerator->MoveNext() == CF_SUCCESS)
   {
      IErrorResult* pValue;
      CFRESULT errorCode = pEnumerator->Current(&pValue);
      pValue->GetError(&errorCode);
      CCfString str;
      pValue->GetName(&str);
   }
}
```

IProcessValue (Page 8003)

ITagCallback (Page 8010)

ITagSetQCDItem (Page 8023)

IErrorResultEnumerator (Page 7999)

ITagSetQCDItem

Description

The C++ interface "ITagSetQCDItem" specifies methods for adapting tags of the Runtime system. You can read in tags into a TagSetQCD and then change all names, values, time stamps and QualityCodes of the tags.

Note

Reaction to external tags

For external tags, only the tag value is set. The QualityCode and time stamp are set internally by the system.

All the methods return CF_SUCCESS following successful execution.

Members

The following methods are specified in the interface:

"GetName" method

Return the name of the tag.

```
CFRESULT GetName(CFSTR *name)
```

`name`
[out]: Points to the name of the tag.

"SetName" method

Change name of the tag.

```
CFRESULT SetName(const CFSTR name)
```

`name`
[in]: New name of the tag.

"GetValue" method

Return value of the tag at the moment of the read operation.

```
CFRESULT GetValue(CFVARIANT *value)
```

`value`
[out]: Points to the process value of the tag.

"SetValue" method

Change value of the tag.

```
CFRESULT SetValue(const CFVARIANT value)
```

`value`
[in]: New process value of the tag.

"GetTimeStamp" method

Return time stamp of the tag.

```
CFRESULT GetTimeStamp(CFDATETIME64 *timeStamp)
```

`timeStamp`
[out]: Points to the time stamp of the tag.

"SetTimeStamp" method

Change time stamp of the tag.

```
CFRESULT SetTimeStamp(const CFDATETIME64 timeStamp)
```

`timeStamp`
[in]: New time stamp of the tag

"GetQuality" method

Return quality code of the read operation of the tag.

```
CFRESULT GetQuality(int32_t *qualityCode)
```

`qualityCode`
[out]: Points to the quality code of the tag.

"SetQuality" method

Change quality code of the tag.

```
CFRESULT SetQuality(const int32_t qualityCode)
```

`qualityCode`
[in]: New quality code of the tag

ITagSetQCD (Page 8019)

ILoggedTagValue

Description

The C++ interface "ILoggedTagValue" specifies the properties that a logged process value of a logging tag has in the logging system.

An "ILoggedTagValue" instance is a pure data object. The instance encapsulates all properties of the logged process value. It represents a historical process value.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

The following methods are specified in the interface:

"GetTagName" method

Return name of the logging tag.

```
CFRESULT GetTagName(CFSTR *value)
```

`value`
[out]: Points to the name of the process value belonging to the logging tag.

"GetValue" method

Return process value of the logging tag.

```
CFRESULT GetValue(CFVARIANT *value)
```

`value`
[out]: Points to the process value of the logging tag.

"GetQuality" method

Return quality code of the process value.

```
CFRESULT GetQuality(int16_t *value)
```

`value`
[out]: Points to the quality code of the process value.

If the "ILoggedTagValue" instance has been added to the log by calling the "Write" method, "Quality" has the value "GOOD" (sub-status: "Unspecific", extended sub-status: "Manual input"). The "Source time" marker is set to "1".

"GetTimeStamp" method

Return time stamp of the process value.

```
CFRESULT GetTimeStamp(CFDATETIME64 *value)
```

`value`
[out]: Points to the time stamp of the process value.

"GetError" method

Return error code of the process value.

```
CFRESULT GetError(uint32_t *value)
```

`value`
[out]: Points to the error code of the process value.

"GetFlags" method

Return context information from the read operation for the process value.

```
CFRESULT GetFlags(HmiTagLoggingValueFlags *value)
```

`value`
[out]: Points to the context information.

The "HmiTagLoggingValueFlags" enumeration contains the following bit-by-bit-coded values:

- 0: `Extra`
  There are still additional values at the time of the process value.
- 2: `Calculated`
  Process value is calculated.
- 16: `Bounding`
  Process value is a limit value.
- 32: `NoData`
  No additional information available
- 64: `FirstStored`
  Process value is the first value stored in the logging system.
- 128: `LastStored`
  Process value is the last value stored in the logging system.

Example

Output process values of a logging tag:

Copy code

```
void PrintValues(ILoggedTagValueEnumeratorPtr pItems,IRuntimePtr pRuntime)
{
   // Iterate over the process value objects
   while (CF_SUCCEEDED(pItems->MoveNext()))
   {
      ILoggedTagValuePtr pValue;
      pItems->Current(&pValue);   // get current process value
      uint32_t nerror;
      pValue->GetError(&nerror);
      if (nerror)
      {
         PrintErrorInformation(nerror, L"GetObject", pRuntime);
         CCfString strName;
         pValue->GetTagName(&strName);
         std::wcout << "Tag With Error: "<<strName.ToUTF8().c_str() << std::endl;
         continue;
      }
      CCfString timeStamp;
      CFDATETIME64 cfTimeStamp;
      pValue->GetTimeStamp(&cfTimeStamp);
      CCfDateTime64 time(cfTimeStamp);
      timeStamp = time.GetDateTimeString(false);
      CCfString strName;
      pValue->GetTagName(&strName);
      CCfVariant varValue;
      pValue->GetValue(&varValue);
      HmiTagLoggingValueFlags enumflag;
      pValue->GetFlags(&enumflag);
      std::wcout << strName.ToUTF8().c_str() << L" " << timeStamp.ToUTF8().c_str() << L"
Value: " << (double)(varValue) <<" Flagvalue = "<< enumflag<< std::endl;
   }
}
```

ILoggedTagValueEnumerator (Page 8027)

ILoggedTag (Page 8032)

ILoggedTagValueEnumerator

Description

The "ILoggedTagValueEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of process values of a logging tag of the Runtime system. The methods are used by the C++-interfaces "ILoggedTag" and "ILoggedTagSet".

All the methods return CF_SUCCESS in case of successful execution.

Members

The following methods are specified in the interface:

"Current" method

Output the current element of the enumeration of a list.

```
CFRESULT Current(ILoggedTagValue **ppItem)
```

`ppItem`
[out]: Points to the current "ILoggedTagValue" object as an element of the list.

"MoveNext" method

Go to the next element of the enumeration of a list.

```
CFRESULT MoveNext()
```

"Reset" method

Reset the current position in the enumeration of a list.

```
CFRESULT Reset()
```

The "MoveNext"method subsequently moves to the first element of the list.

"Count" method

Output the size of the enumeration or the number of elements of a list.

```
CFRESULT Count(uint32_t *value)
```

`value`
[out]: Points to the value for the number of the elements of the list.

Example

Output process values of a logging tag:

Copy code

```
void PrintValues(ILoggedTagValueEnumeratorPtr pItems,IRuntimePtr pRuntime)
{
   // Iterate over the process value objects
   while (CF_SUCCEEDED(pItems->MoveNext()))
   {
      ILoggedTagValuePtr pValue;
      pItems->Current(&pValue);   // get current process value
      ...
   }
}
```

ILoggedTagSet (Page 8033)

ILoggedTagCallback / ILoggedTagSetCallback (Page 8028)

ILoggedTagCallback / ILoggedTagSetCallback

Description

The interfaces "ILoggedTagCallback" and "ILoggedTagSetCallback" and the classes "COdkTagSourceCBBase" and "COdkTagSetLoggingCB" define methods for implementing asynchronous read and write operations with logging tags. The methods are used by the C++-interfaces "ILoggedTag" and "ILoggedTagSet".

All the methods return CF_SUCCESS following successful execution.

Members of "ILoggedTagCallback"

The following methods are specified in the interface:

"OnReadComplete" method

Callback method is called on completion of asynchronous read operations.

```
CFRESULT OnReadComplete(ILoggedTagValueEnumerator *pEnumerator)
```

`pEnumerator`
[out]: Points to an "ILoggegTagValueEnumerator" object that contains the enumeration of the process values.

"OnDeleteComplete" method

Callback method is called on completion of asynchronous delete operations.

```
CFRESULT OnDeleteComplete(ILoggedTagValueEnumerator *pEnumerator)
```

`pEnumerator`
[out]: Points to an "ILoggegTagValueEnumerator" object that contains the enumeration of the process values.

"OnWriteComplete" method

Callback method is called on completion of asynchronous write operations. Can only be applied to individual logging tags in the "ILoggedTagCallback" interface.

```
CFRESULT OnWriteComplete(ILoggedTagValueEnumerator *pEnumerator)
```

`pEnumerator`
[out]: Points to an "ILoggegTagValueEnumerator" object that contains the enumeration of the process values.

"OnDataChanged" method

Callback method is called when a monitored logging tag is changed.

```
CFRESULT OnDataChanged(ILoggedTagValueEnumerator *pEnumerator)
```

`pEnumerator`
[out]: Points to an "ILoggegTagValueEnumerator" object that contains the enumeration of the process values.

Members of "ILoggedTagSetCallback"

The following methods are specified in the interface:

"OnReadComplete" method

Callback method is called on completion of asynchronous read operations.

The "OnReadComplete" callback method is called when the "ReadAsync" method is used.

```
CFRESULT OnReadComplete(ILoggedTagValueEnumerator *pEnumerator,
         uint32_t errorCode,
         int32_t contextId)
```

- `pEnumerator`
  [out]: Points to an "ILoggegTagValueEnumerator" object that contains the enumeration of the process values.
- `errorCode`
  [out]: Error code for the asynchronous operation
- `contextId`
  [out]: ContextID as additional identification feature of the logging tag.

"OnDataChanged" method

Callback method is called when a monitored logging tag is changed.

The callback method is called after the process value change of a monitored logging tag or a LoggedTagSet.

```
CFRESULT OnDataChanged(ILoggedTagValueEnumerator *pEnumerator,
         uint32_t errorCode,
         int32_t contextId)
```

- `pEnumerator`
  [out]: Points to an "ILoggegTagValueEnumerator" object that contains the enumeration of the process values.
- `errorCode`
  [out]: Error code for the asynchronous operation
- `contextId`
  [out]: ContextID as additional identification feature of the logging tag.

Members of the classes

The following methods are implemented in the "COdkTagSourceCBBase" and "COdkTagSetLoggingCB" classes:

"SetEvent" method

Signals an event.

```
CFBOOL SetEvent()
```

"ResetEvent" method

Resets the signaling of an event.

```
CFBOOL ResetEvent()
```

"WaitForcompletion" method

Waits for the signaling of an event.

```
uint32_t WaitForcompletion(uint32_t dwMilliseconds)
```

`dwMilliseconds`
[in]: Time interval in milliseconds for which an event is waited for.

"GetValues" method

Return process values of the asynchronous read operation.

```
std::vector<ILoggedTagValuePtr> GetValues()
```

Example

Output LoggedTagSet asynchronously:

Copy code

```
void LogggingReadTagSetAsync(IRuntimePtr pRuntime, std::vector<CCfString> tags)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"LoggedTagSet"), &pUnk);

   ILoggedTagSetPtr pTagSet(pUnk);
   // add tags to tag set
   for (int i = 0; i < tags.size(); i++)
   {
      pTagSet->Add(tags[i]);
   }
   CCfDateTime64 begin, end;
   begin = CCfDateTime64::Now(true);
   end = begin;
   begin.SubtractTimeSpan(Get1Minute() * 30);

   ILoggedTagValueEnumeratorPtr pItems;

   COdkTagSetLoggingCB* pTagSetCB = new COdkTagSetLoggingCB();

   pTagSetCB->AddRef();
   // Read the tag set asynchronously, result comes via callback
   pTagSet->ReadAsync(pTagSetCB, begin, end, true);
   pTagSetCB->WaitForcompletion(std::numeric_limits<uint32_t>::max());
   vector<ILoggedTagValuePtr> pValues = pTagSetCB->GetValues();

   // display tag values
   for (int i = 0; i < pValues.size(); i++)
   {
      ILoggedTagValue* pValue = pValues[i];
      CCfString timeStamp;
      CFDATETIME64 cfTimeStamp;
      pValue->GetTimeStamp(&cfTimeStamp);
      CCfDateTime64 time(cfTimeStamp);
      timeStamp = time.GetDateTimeString(false);
      CCfString strName;
      pValue->GetTagName(&strName);
      CCfVariant varValue;
      pValue->GetValue(&varValue);
      std::wcout << strName.ToUTF8().c_str() << L" " << timeStamp.ToUTF8().c_str() << L"
Value: " << (double)(varValue) << std::endl;
   }
}
```

ILoggedTag (Page 8032)

ILoggedTagSet (Page 8033)

ILoggedTagValueEnumerator (Page 8027)

ILoggedTag

Description

The C++ interface "ILoggedTag" specifies properties and methods for the handling of logging tags of a logging system. A logging tag is represented by an "ILoggedTag" instance. The information on the logged process values of the logging tag is stored in "ILoggedTagValue" instances.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

The following methods are specified in the interface:

"SetTagName" method

Set name of the logging tag.

```
CFRESULT SetTagName(const CFSTR tagName)
```

`tagName`
[in]: Name of the logging tag

"Read" method

Synchronous read operation to read the "ILoggedTagValue" instances of the logging tag whose time stamps are in the time period defined by the arguments.

```
CFRESULT Read(
         const CFTIMEDATE64 begin,
         const CFTIMEDATE64 end,
         ILoggedTagValueEnumerator** ppEnumerator,
         CFBOOL boundingValue)
```

- `begin`
  [in]: Start date of the time period
- `end`
  [in]: End date of the time period
- `ppEnumerator`
  [in/out]: Points to the enumeration of "ILoggedTagValue" instances of the logging tag as "ILoggedTagValueEnumerator" object.
- `boundingValue`
  [in]: True, in order to additionally return high and low limits.

"Write" method

Synchronous write operation.

The method manually writes an "ILoggedTagValue" instance to the logging system. "Quality" of the instance receives the value "GOOD" (sub-status: "Unspecific", extended sub-status: "Manual input"). The "Source time" marker is set to "1".

Application example: While the connection to the logging system is interrupted, the process value of a tag that is being logged changes. The resulting "ILoggedTagValue" instance is cached. After the connection has been re-established, manually add the instance to the log by calling "Write".

```
CFRESULT Write(
         ILoggedTagValue* ptag
```

- `ptag`
  [in]: The "ILoggedTagValue" instance to be logged

Example

Read out process values of a logging tag synchronously from a logging system:

Copy code

```
void LoggingReadSingleTagSync(IRuntimePtr pRuntime, CCfString tag)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"LoggedTag"), &pUnk);
   ILoggedTagPtr pTag(pUnk);
   pTag->SetTagName(tag);
   CCfDateTime64 begin, end;
   begin = CCfDateTime64::Now(true);
   end = begin;
   begin.SubtractTimeSpan(Get1Minute() * 3);
   ILoggedTagValueEnumeratorPtr pItems;
   // Read value of tag
   pTag->Read(begin, end, &pItems, true);
   std::wcout << "Read finished " << std::endl;
   PrintValues(pItems ,pRuntime);
}
```

ILoggedTagValue (Page 8024)

ILoggedTagSet (Page 8033)

ILoggedTagCallback / ILoggedTagSetCallback (Page 8028)

ILoggedTagValueEnumerator (Page 8027)

ILoggedTagSet

Description

The C++ interface "ILoggedTagSet" specifies properties, methods and events for optimized access to a collection of "ILoggedTag" instances of a logging system.

After initializing an "ILoggedTagSet" instance, you can read or write multiple "ILoggedTag" instances in one call. Simultaneous access demonstrates better performance and lower communication load than single access to multiple logging tags.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

The following methods are specified in the interface:

"SetContextId" method

ID as additional identification feature of the logging tag. The ContextId can, for example, be used to recognize identically named logging tags from different monitoring functions. Default value -1: The ContextId is not used.

```
CFRESULT SetContextId(const int32_t value)
```

`value`
[in]: ContextId of the logging tag

"GetContextId" method

ID as additional identification feature of the logging tag. The ContextId can, for example, be used to recognize identically named logging tags from different monitoring functions. Default value -1: The ContextId is not used.

```
CFRESULT GetContextId(int32_t* value)
```

`value`
[out]: Points to the ContextId of the logging tag.

"Add" method

The method is overloaded:

- Add a single "ILoggedTag" instance to the "ILoggedTagSet" instance:
  `CFRESULT Add(const CFSTR tagName)`
  `tagName`
  [in]: Name of the "ILoggedTag" instance
- Add an "ILoggedTagValue" instance to the "ILoggedTagSet" instance:
  `CFRESULT Add(ILoggedTagValue* object)`
  `object`
  [in]: Reference of the "ILoggedTagValue" instance

"Remove" method

Remove individual logging tag from a LoggedTagSet.

```
CFRESULT Remove(const CFSTR tagName)
```

`tagName`
[in]: Name of the logging tag that is removed from the LoggedTagSet.

"Clear" method

Remove all logging tags from a LoggedTagSet.

```
CFRESULT Clear()
```

"Read" method

Retrieve all logging tags of a LoggedTagSet for a period of time synchronously from the logging system.

```
CFRESULT Read(
         const CFTIMEDATE64 begin,
         const CFTIMEDATE64 end,
         ILoggedTagValueEnumerator** ppEnumerator,
         CFBOOL boundingValue)
```

- `begin`
  [in]: Start date of the time period
- `end`
  [in]: End date of the time period
- `ppEnumerator`
  [in/out]: Points to the enumeration of process values of the logging tags of the LoggedTagSet as "ILoggedTagValueEnumerator" object.
- `boundingValue`
  [in/optional]: True, in order to additionally return high and low limits.

"ReadAsync" method

Retrieve all logging tags of a LoggedTagSet for a period of time synchronously from the logging system.

```
CFRESULT ReadAsync(
         ILoggedTagSetCallback *pTagLoggedCb,
         const CFTIMEDATE64 begin,
         const CFTIMEDATE64 end,
         CFBOOL boundingValue)
```

- `pTagLoggedCb`
  [in]: Points to the "ILoggedTagSetCallback" object that implements the callback interface.
- `begin`
  [in]: Start date of the time period
- `end`
  [in]: End date of the time period
- `boundingValue`
  [in/optional]: True, in order to additionally return high and low limits.

"Subscribe" method

Subscribe all logging tags of a LoggedTagSet asynchronously for updating the process values following a change. When new process values are logged, they can be processed with the "OnDataChanged" event.

```
CFRESULT Subscribe(ILoggedTagSetCallback* pTagSetLoggedCb)
```

`pTagSetLoggedCb`
[in]: Points to the "ILoggedTagSetCallback" object that implements the callback interface.

"CancelSubscribe" method

Cancel updating of process values following a change for all logging tags of a LoggedTagSet.

```
CFRESULT CancelSubscribe()
```

"Write" method

Synchronous write operation.

Writes the "ILoggingTagValue" instances added by call of "Add" to the logging system. "Quality" of the instance receives the value "GOOD" (sub-status: "Unspecific", extended sub-status: "Manual input"). The "Source time" marker is set to "1".

Errors during write operations are returned in a list with "IErrorResult" instances.

Application example: The connection to the archive server was interrupted. After the connection has been re-established, add multiple "ILoggedTagValue" instances cached in the PLC to the archive afterwards by calling "Write".

```
CFRESULT Write(IErrorResultEnumerator** ppErrorEnumerator)
```

`ppErrorEnumerator`
[out]: Points to an "IErrorResultEnumerator" object that contains the enumeration with errors for the write operations.

"WriteAsync" method

Asynchronous write operation.

Writes the "ILoggingTagValue" instances added by call of "Add" to the logging system. "Quality" of the instance receives the value "GOOD" (sub-status: "Unspecific", extended sub-status: "Manual input"). The "Source time" marker is set to "1".

Application example: The connection to the archive server was interrupted. After the connection has been re-established, add multiple "ILoggedTagValue" instances cached in the PLC to the archive afterwards by calling "Write".

```
CFRESULT WriteAsync(ILoggedTagSetCallback* pTagLoggedCb)
```

`pTagLoggedCb`
[in]: Points to the "ILoggedTagSetCallback" object that implements the callback interface.

"GetCount" method

Return the number of logging tags of a LoggedTagSet list.

```
CFRESULT GetCount(int32_t *value)
```

`value`
[out]: Points to the value for the number of logging tags of the LoggedTagSet list.

Example

Subscribe logging tags of a LoggedTagSet for change monitoring:

Copy code

```
void LoggingSubscribeTagSet(IRuntimePtr pRuntime, std::vector<CCfString> tags)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"LoggedTagSet"), &pUnk);
   ILoggedTagSetPtr pTagSet(pUnk);
   // add tags to tag set
   for (int i = 0; i < tags.size(); i++)
   {
      pTagSet->Add(tags[i]);
   }
   COdkTagSetLoggingCB* pTagSetCB = new COdkTagSetLoggingCB();
   pTagSetCB->AddRef();
   // subscribe tags
   pTagSet->Subscribe(pTagSetCB);
   //stop subscription
   pTagSet->CancelSubscribe();
}
```

See also

ILoggedTag (Page 8032)

ILoggedTagCallback / ILoggedTagSetCallback (Page 8028)

ILoggedTagValueEnumerator (Page 8027)

ITags

Description

The C++ interface "ITags" defines methods with which you can access configured tags.

The interface inherits from the "ICfDispatch" interface.

All the methods return `CF_SUCCESS` following successful execution. In the case of an error, the methods return the corresponding error code.

Members

"Find" method

Supplies an enumerator for access to the "ITagAttributes" instances of the specified tag.

```
CFRESULT Find(
         CFVARIANT systemIDs,
         int32_t language,
         CFSTR filter,
         ITagAttributesEnumerator** ppITagAttributesEnumerator)
```

```
Find(CFVARIANT systemIDs, uint32_t language, CFSTR filter,
ITagAttributesEnumerator** ppITagAttributesEnumerator)
```

- `systemIDs`
  [in]: Collection of SystemNames on which the tags were configured.
- `language`
  [in]: Language code ID of filter
- `filter`
  [in]: Filter by name of the tags to restrict the search.
  Supports searching with wildcard (*)
- `ppITagAttributesEnumerator`
  [out]: Enumerator which supplies access to the "ITagAttributes" instances.

"FindAsync" method

For asynchronous searching for "ITagAttributes" instances of the specified tags.

```
FindAsync(
         CFVARIANT systemIDs
         uint32_t language
         CFSTR filter
         ITagAttributesCallback* pCallback)
```

- `systemIDs`
  [in]: Collection of SystemNames on which the tags were configured.
- `language`
  [in]: Language code ID of filter
- `filter`
  [in]: Filter by name of the tags to restrict the search.
  Supports searching with wildcard (*)
- `filterpCallback`:
  [in]: Callback pointer to an "ITagAttributesCallback" instance

ITagAttributes

Description

The C++ interface "ITagAttributes" defines methods for access to the attributes of a tag.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

"GetName" method

Supplies the name of the tags. Must be unique throughout the device.

```
GetName(
         CFSTR* name)
```

- `name`
  [out]: The name

"GetDisplayName" method

Supplies the display name of the tags.

```
GetDisplayName(
         CFSTR* name)
```

- `name`
  [out]: The display name

"GetDataType" method

Supplies the data type of the tags.

```
GetDataType(
         CFENUM* datatype)
```

- `datatype`
  [out]: The data type of the tag

"GetConnection" method

Supplies the connection of the tag.

The memory location of the tag in the controller is accessed via the connection.

```
GetConnection(
         CFSTR* connection)
```

- `connection`
  [out]: The connection

"GetAcquisitionCycle" method

Specifies the tag acquisition cycle.

If you configure a tag at an object, the acquisition cycle of the tag is displayed at the object.

```
GetAcquisitionCycle(
         CFSTR* acquisitionCycle)
```

- `acquisitionCycle`
  [out]: The acquisition cycle

"GetAcquisitionMode" method

Supplies the acquisition mode of the tag.

```
GetAcquisitionMode(
         CFENUM* acquisitionMode)
```

- `acquisitionMode`
  [out]: Value of the enumeration "HmiAcquisitionMode".
  The enumeration "HmiAcquisitionMode" can contain the following values:
  - Undefined (0)
  - CyclicOnUse (1)
  - CyclicContinous (2)
  - OnDemand (3)
  - OnChange (4)

"GetMaxLength" method

Supplies the length of the tags.

The length is only available with a string tag. The length is preset for structure tags and cannot be changed.

```
GetMaxLength(
         uint32_t* maxLength)
```

- `maxLength`
  [out]: Maximum length

"GetPersistent" method

Supplies the persistence of the tags.

```
GetPersistent(
         CFBOOL* persistent)
```

- `persistent`
  [out]: The persistence

"GetInitialValue" method

Supplies the start value of the tag.

After Runtime starts, the tag retains the start value until an operator or the PLC changes the value.

```
GetInitialValue(
        CFVARIANT * initialValue)
```

- `initialValue`
  [out]: The start value

"GetInitialMaxValue" method

Supplies the start value for the event "On exceeding".

```
InitialMaxValue(
        CFVARIANT * initialValue)
```

- `initialValue`
  [out]: The start value

"GetInitialMinValue" method

Supplies the start value for the event "On falling below".

```
InitialMinValue(
        CFVARIANT * initialValue)
```

- `initialValue`
  [out]: The start value

"GetSubstituteValue" method

Supplies the substitute value of the tags.

If the selected condition occurs, the tag is filled with the substitute value in runtime.

```
GetSubstituteValue(
        CFVARIANT * substituteValue)
```

- `substituteValue`
  [out]: The substitute value

"GetSubstituteValueUsage" method

Supplies the condition for the use of the substitute value of the tag.

```
GetSubstituteValueUsage(
        CFVARIANT * substituteValueUsage)
```

- `substituteValueUsage`
  [out]: The condition

ITagAttributesEnumerator

Description

The "ITagAttributesEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of tag attributes. The enumerator enables access to individual attributes from a set of tag attributes.

The interface inherits from the "ICfUnknown" interface.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

"MoveNext" method

Go to the next element of the enumerator.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumerator

```
CFRESULT Current(
         ITagAttributes** ppItem)
```

- `ppItem`
  [out]: The current "ITagAttributes" instance

"Reset" method

Reset the current position in the enumerator. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumerator or the number of its elements.

```
CFRESULT Count(
         uint32_t* value)
```

- `value`
  [out]: Number of attributes

ITagAttributesCallback

Description

The C++ interface "ITagAttributesCallback" defines the callback method "OnTagAttributesRead". The method is used for implementing asynchronous read operations of tag attributes. The method is used by the C++ interface "ITags".

The interface implements the methods of the "ICfUnknown" interface.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

"OnTagAttributesRead" method

Callback method, is called on completion of an asynchronous search for "ITagAttributes" instances.

```
OnTagAttributesRead(
         ITagAttributesEnumerator* pEnumerator,
         CFBOOL bIsCompleted)
```

- `ITagAttributesEnumerator`
  [in/out]: Reference to an "ITagAttributesEnumerator" instance which provides access to the tag attributes.
- `bIsCompleted`
  [out]: Supplies information on whether the read operation was successfully completed.

ILoggingTags

Description

The C++ interface "ILoggingTags" defines methods with which you can access configured logging tags.

The interface inherits from the "ICfDispatch" interface.

All the methods return `CF_SUCCESS` following successful execution. In the case of an error, the methods return the corresponding error code.

Members

"Find" method

Supplies an enumerator for access to the "ITagAttributes" instances of the specified logging tag.

```
CFRESULT Find(
         CFVARIANT systemIDs,
         uint32_t language,
         CFSTR filter,
        ILoggingTagAttributesEnumerator** ppILoggingTagAttributesEnumerator)
```

- `systemIDs`
  [in]: Collection of SystemNames on which the logging tags were configured.
- `language`
  [in]: Language code ID of filter
- `filter`
  [in]: Filter by name of the logging tags to restrict the search.
  Supports searching with wildcard (*).
  Example:
  `Tag1:*` Supplies all logging tags of "Tag1".
- `ppILoggingTagAttributesEnumerator`
  [out]: Enumerator which supplies access to the "ILoggingTagAttributes" instances.

"FindAsync" method

For asynchronous searching for "ILoggingTagAttributes" instances.

```
CFRESULT FindAsync(CFVARIANT systemIDs,
         uint32_t language,
         CFSTR filter,
         ILoggingTagAttributesCallback* pCallback)
```

- `systemIDs`
  [in]: Collection of SystemNames on which the logging tags were configured.
- `language`
  [in]: Language code ID of filter

- `filter`
  [in]: Filter by name of the logging tags to restrict the search.
  Supports searching with wildcard (*).
- pCallback
  [in]: Callback pointer to an "ILoggingTagAttributesCallback" instance

ILoggingTagAttributes

Description

The C++ interface "ITagAttributes" defines methods for access to the attributes of a logging tag.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

"GetName" method

Supplies the name of the logging tag.

```
GetName(
         CFSTR* name)
```

- `name`
  [out]: The name

"GetDisplayName" method

Supplies the display name of the logging tags.

```
GetDisplayName(
         CFSTR* name)
```

- `name`
  [out]: The display name

"GetDataType" method

Supplies the data type of the logging tags.

```
GetDataType(
         CFENUM* datatype)
```

- `datatype`
  [out]: The data type

ILoggingTagAttributesEnumerator

Description

The "ILoggingTagAttributesEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of logging tag attributes. The enumerator enables access to individual attributes from a set of tag attributes.

The interface inherits from the "ICfUnknown" interface.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

"MoveNext" method

Go to the next element of the enumerator.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumerator

```
CFRESULT Current(
         ITagAttributes** ppItem)
```

- `ppItem`
  [out]: The current "ITagAttributes" instance

"Reset" method

Reset the current position in the enumerator. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumerator or the number of its elements.

```
CFRESULT Count(
         uint32_t* value)
```

- `value`
  [out]: Number of attributes

ILoggingTagAttributesCallback

Description

The C++ interface "ILoggingTagAttributesCallback" defines the callback method "OnTagAttributesRead". The method is used for implementing asynchronous read operations of logging tag attributes. The method is used by the C++ interface "ILoggingTags".

The interface implements the methods of the "ICfUnknown" interface.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

"OnTagAttributesRead" method

Callback method, is called on completion of an asynchronous search for "ITagAttributes" instances.

```
OnTagAttributesRead(
          ILoggingTagAttributesEnumerator* pEnumerator,
          CFBOOL bIsCompleted)
```

- `ILoggingTagAttributesEnumerator`
  [in]: Reference to an "ILoggingTagAttributesEnumerator" instance which provides access to the tag attributes.
- `bIsCompleted`
  Supplies information on whether the result of the read operation is complete or whether other events will come.

20.3.9.4 Interfaces of the alarms

IAlarmResult

Description

The C++ interface "IAlarmResult" specifies methods for accessing properties of active alarms of the runtime system.

An "IAlarmResult" object is a pure data object which maps all properties of an active alarm.

Members

The following methods are specified in the interface:

"GetInstanceID" method

Return InstanceID for an alarm with multiple instances.

```
CFRESULT GetInstanceID(uint32_t *value)
```

`value`
[out]: Points to the InstanceID of the alarm.

"GetSourceID" method

Return source at which the alarm was triggered.

```
CFRESULT GetSourceID(CFSTR *value)
```

`value`
[out]: Points to the source of the alarm.

"GetName" method

Return the name of the alarm.

```
CFRESULT GetName(CFSTR *value)
```

`value`
[out]: Points to the name of the alarm.

"GetAlarmClassName" method

Return the name of the alarm class.

```
CFRESULT GetAlarmClassName(CFSTR *value)
```

`value`
[out]: Points to the symbol of the associated alarm class.

"GetAlarmClassSymbol" method

Return the symbol of the alarm class.

```
CFRESULT GetAlarmClassSymbol(CFSTR *value)
```

`value`
[out]: Points to the name of the associated alarm class.

"GetState" method

Return current alarm state.

```
CFRESULT GetState(int32_t *value)
```

`value`
[out]: Points to the current alarm state.

"GetStateText" method

Return current alarm state as text, for example, "active" or "inactive".

```
CFRESULT GetStateText(CFSTR *value)
```

`value`
[out]: Points to the current alarm state as text.

"GetEventText" method

Return text that describes the alarm event.

```
CFRESULT GetEventText(CFSTR *value)
```

`value`
[out]: Points to the text that describes the alarm event.

"GetInfoText" method

Return text that describes the alarm event.

```
CFRESULT GetInfoText(CFSTR *value)
```

`value`
[out]: Points to the text that describes an operator instruction for the alarm.

"GetAlarmText1" ... "GetAlarmText9" method

Return additional texts 1-9 of the alarm.

```
CFRESULT GetAlarmText1(CFSTR *value)
```

...

```
CFRESULT GetAlarmText9(CFSTR *value)
```

`value`
[out]: Points to the additional text of the alarm.

"GetTextColor" method

Return text color of the alarm state.

```
CFRESULT GetTextColor(uint32_t *value)
```

`value`
[out]: Points to the text color of the alarm state.

"GetBackColor" method

Return background color of the alarm state.

```
CFRESULT GetBackColor(uint32_t *value)
```

`value`
[out]: Points to the background color of the alarm state.

"GetFlashing" method

Return flashing background color of the alarm state.

```
CFRESULT GetFlashing(CFBOOL *value)
```

`value`
[out]: Points to the flashing background color of the alarm state.

"GetModificationTime" method

Return time of the last modification to the alarm state.

```
CFRESULT GetModificationTime(CFDATETIME64 *value)
```

`value`
[out]: Points to the time of the last change of the alarm state.

"GetChangeReason" method

Return trigger event for modification of the alarm state.

```
CFRESULT GetChangeReason(uint16_t *value)
```

`value`
[out]: Points to the trigger event for the change of the alarm state.

"GetRaiseTime" method

Return trigger time of the alarm.

```
CFRESULT GetRaiseTime(CFDATETIME64 *value)
```

`value`
[out]: Points to the time the alarm was triggered.

"GetAcknowledgementTime" method

Return time of alarm acknowledgment.

```
CFRESULT GetAcknowledgementTime(CFDATETIME64 *value)
```

`value`
[out]: Points to the time of alarm acknowledgment.

"GetClearTime" method

Return time of the alarm reset.

```
CFRESULT GetClearTime(CFDATETIME64 *value)
```

`value`
[out]: Points to the time of the alarm reset.

"GetResetTime" method

Return time of the alarm reset.

```
CFRESULT GetResetTime(CFDATETIME64 *value)
```

`value`
[out]: Points to the time of the alarm reset.

"GetSuppressionState" method

Return status of alarm visibility.

```
CFRESULT GetSuppressionState(uint8_t *value)
```

`value`
[out]: Points to the status of the alarm visibility.

"GetPriority" method

Return relevance for display and sorting of the alarm.

```
CFRESULT GetPriority(uint8_t *value)
```

`value`
[out]: Points to the relevance of the alarm.

"GetOrigin" method

Return origin for display and sorting of the alarm.

```
CFRESULT GetOrigin(CFSTR *value)
```

`value`
[out]: Points to the origin of the alarm.

"GetArea" method

Return origin area for display and sorting of the alarm.

```
CFRESULT GetArea(CFSTR *value)
```

`value`
[out]: Points to the origin area of the alarm.

"GetValue" method

Return the current process value of the alarm.

```
CFRESULT GetValue(CFVARIANT *value)
```

`value`
[out]: Points to the current process value of the alarm.

"GetValueQuality" method

Return quality of the process value of the alarm.

```
CFRESULT GetValueQuality(uint16_t *value)
```

`value`
[out]: Points to the quality of the process value of the alarm.

"GetValueLimit" method

Return process value limit of the alarm.

```
CFRESULT GetValueLimit(CFVARIANT *value)
```

`value`
[out]: Points to the limit of the process value of the alarm.

"GetUserName" method

Return the user name of the operator input alarm.

```
CFRESULT GetUserName(CFSTR *value)
```

`value`
[out]: Points to the user name of the operator input alarm.

"GetLoopInAlarm" method

Return function that navigates from the alarm control to its origin.

```
CFRESULT GetLoopInAlarm(CFSTR *value)
```

`value`
[out]: Points to the function name that navigates to the origin of the alarm.

"GetAlarmParameterValues" method

Return parameter values of the alarm.

```
CFRESULT GetAlarmParameterValues(CFVARIANT *value)
```

`value`
[out]: Points to the parameter values of the alarm.

"GetInvalidFlags" method

Return identification of the alarm with invalid data.

```
CFRESULT GetInvalidFlags(uint8_t *value)
```

`value`
[out]: Points to the invalid data of the alarm.

"GetConnection" method

Return connection via which the alarm was triggered.

```
CFRESULT GetConnection CFSTR *value)
```

`value`
[out]: Points to the connection of the alarm.

"GetSystemSeverity" method

Return severity of the system error.

```
CFRESULT GetSystemSeverity(uint8_t *value)
```

`value`
[out]: Points to the severity of the system error.

"GetUserResponse" method

Return expected or required user response to the alarm.

```
CFRESULT GetUserResponse(uint8_t *value)
```

`value`
[out]: Points to the expected or required user response to the alarm.

"GetSourceType" method

Return source from which the alarm was generated, for example, tag-based, controller-based or system-based alarm.

```
CFRESULT GetSourceType(uint16_t *value)
```

`value`
[out]: Points to the type of source.

"GetDeadBand" method

Return range of the triggering tag in which no alarms are generated.

```
CFRESULT GetDeadBand(CFVARIANT *value)
```

`value`
[out]: Points to the non-triggering range.

"GetId" method

Return ID of the alarm that is also used in the display.

```
CFRESULT GetId(uint32_t *value)
```

`value`
[out]: Points to the ID of the alarm.

"GetAlarmGroupID" method

Return ID of the alarm group to which the alarm belongs.

```
CFRESULT GetAlarmGroupID(uint32_t* groupId)
```

`groupId`
[out]: The ID of the alarm group

"GetHostName" method

Return the name of the host that triggered the alarm.

```
CFRESULT GetHostName(CFSTR *value)
```

`value`
[out]: Points to the host name.

"GetNotificationReason" method

Return the reason for the notification.

```
CFRESULT GetNotificationReason(CFENUM* value)
```

`value`:
[out]: Points to the enumeration of the notification reason. The notification reason can have the following values:

- `Unknown` (0)
- `Add` (1)
  The alarm was added to the filtered result list. The alarm meets the filter criteria that apply to the monitoring.
- `Modify` (2)
  Properties of the alarm were changed, but the alarm is still part of the filtered result list.
- `Remove` (3)
  The alarm was part of the result list, but it no longer meets the filter criteria due to changes to its properties.

  Note

  Changes to the alarms only lead to notifications again when the alarm meets the filter criteria again. In this case, "NotificationReason" is set to `Add`.

Note

Removing alarm from business logic

The use case of the client determines whether the client ignores notifications via alarms with the "NotificationReason" `Modify` or `Remove`.

For example:

- State-based monitoring: The client wants to show a list of incoming alarms. All notification reasons are relevant. The client removes an alarm from the list as soon as the notification reason is `Remove`.
- Event-based monitoring: The client wants to send an email when an alarm comes in. Only the notification reason `Add` is relevant.

Example:

An ODK client begins monitoring with the filter criterion "State" = 1. An alarm is triggered. Runtime notifies the ODK client of the "NotificationReason" as follows:

Notification-Reason	Description
Add	• The "State" property is 1. The alarm is active.
Modify	• The "State" property has not changed. • Another property that is not part of the filter criterion has changed, e.g. "Priority".
Remove	The "State" property has changed, for example, alarm is inactive.

Method "GetDuration"

Returns the time interval in nanoseconds between triggering of the alarm and its previous status change.

```
CFRESULT GetDuration(CFTIMESPAN64 *value)
```

`value`
[out]: The time interval in nanoseconds

Example

When alarms become active, a selection of properties of the "IAlarmResult" objects is output:

Copy code

```
// Callback for alarm notifications
CFRESULT CFCALLTYPE CAlarmValue::OnAlarm(IAlarmResultEnumerator* pItems, uint32_t
systemError, CFSTR systemName, CFBOOL completed)
{
    CFRESULT hr = CF_FALSE;
    CFBOOL bSet = false;
    uint32_t nsize;
    pItems->Count(&nsize);

    if (nsize > 0 && CF_SUCCEEDED(systemError)) {
        m_AlarmValue.clear();

        while (CF_SUCCEEDED(pItems->MoveNext()))
        {
            IAlarmResultPtr ppValues;
            pItems->Current(&ppValues);

            AlarmAttributes AlarmValue;
            AlarmValue.m_nInstanceID;
            ppValues->GetInstanceID(&AlarmValue.m_nInstanceID);
            AlarmValue.m_strSourceID;
            CCfString strId;
            ppValues->GetSourceID(&strId);
            AlarmValue.m_strSourceID = CCfSmartString(strId);
            CCfString strName;
            ppValues->GetName(&strName);
            AlarmValue.m_strName = CCfSmartString(strName);
            CCfString strClassName;
            ppValues->GetAlarmClassName(&strClassName);
            AlarmValue.m_strAlarmClassName = CCfSmartString(strClassName);
            ppValues->GetState(&AlarmValue.m_nState);
            CCfString strEvent;
            ppValues->GetEventText(&strEvent);
            AlarmValue.m_strEventText = CCfSmartString(strEvent);
            CCfString strText;
            ppValues->GetStateText(&strText);
            AlarmValue.m_strStateText = CCfSmartString(strText);
            ppValues->GetBackColor(&AlarmValue.m_nBackColor);
            ppValues->GetTextColor(&AlarmValue.m_nTextColor);
            ppValues->GetFlashing(&AlarmValue.m_bFlashing);
            ppValues->GetDuration(&nDuration);

            ...

            AlarmValue.m_nAlarmsSize = nsize;

            AlarmValue.m_strSystemName = systemName;
           std::cout << "System name = " << AlarmValue.m_strSystemName.ToUTF8().c_str() <<
std::endl;

            m_AlarmValue.push_back(AlarmValue);
            std::cout << "Alarm name = " << strName.ToUTF8().c_str() << std::endl;
        }

        this->SetEvent();
```

Copy code

```
        return CF_SUCCESS;
    }
    return hr;
}
```

IAlarm (Page 8057)

IAlarmSubscription (Page 8077)

IAlarmResultEnumerator

Description

The "IAlarmResultEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of active alarms of the runtime system. Through the enumeration, you access individual alarms from the quantity of all active alarms of the runtime system.

All the methods return CF_SUCCESS following successful execution.

Members

The following methods are specified in the interface:

"Current" method

Output the current element of the enumeration of a list.

```
CFRESULT Current(IAlarmResult **ppItem)
```

`ppItem`
[out]: Points to the current "IAlarmResult" object as an element of the list.

"MoveNext" method

Go to the next element of the enumeration of a list.

```
CFRESULT MoveNext()
```

"Reset" method

Reset the current position in the enumeration of a list.

```
CFRESULT Reset()
```

The "MoveNext" method moves afterwards to the first element of the list.

"Count" method

Output the size of the enumeration or the number of elements of a list.

```
CFRESULT Count(uint32_t *value)
```

`value`
[out]: Points to the value for the number of elements of the list.

IAlarmResult (Page 8046)

IAlarm

Description

The C++ interface "IAlarm" specifies properties and methods for handling active alarms of the runtime system.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

The following methods are specified in the interface:

"SetSourceID" method

Set the ID of the source at which the active alarm was triggered.

```
CFRESULT SetSourceID(CFVARIANT sourceID)
```

`sourceID`
[in]: ID of the source of the active alarm

"SetName" method

Set the name of the active alarm.

```
CFRESULT SetName(CFSTR name)
```

`name`
[in]: Name of the active alarm

"GetName" method

Read out name of the active alarm.

```
CFRESULT GetName(CFSTR *name)
```

`name`
[out]: Points to a name of the active alarm.

"SetErrorCode" method

Set error code of the alarm.

```
CFRESULT SetErrorCode(uint32_t errorCode)
```

`errorCode`
[in]: Error code

"GetError" method

Read out error code of the alarm.

```
CFRESULT GetError(uint32_t *error)
```

`error`
[out]: Error code

"Disable" method

Deactivate generation of the alarm in the alarm source synchronously.

```
CFRESULT Disable()
```

"Enable" method

Activate generation of the alarm in the alarm source again synchronously.

```
CFRESULT Enable()
```

"Shelve" method

Hide active alarm synchronously.

```
CFRESULT Shelve()
```

"Unshelve" method

Display hidden alarm synchronously again.

```
CFRESULT Unshelve()
```

"Acknowledge" method

Acknowledge active alarm or instance of an active alarm synchronously.

```
CFRESULT Acknowledge(uint32_t instanceId)
```

- `instanceId`
  Value "0": Acknowledge all instances of an active alarm.
  Value > "0": Acknowledge instance with this ID.

"Reset" method

Acknowledge the inactive state of an active alarm or an instance of an active alarm synchronously.

```
CFRESULT Reset(uint32_t instanceId)
```

- `instanceId`
  Value "0": Acknowledge the inactive state of the active alarm.
  Value > "0": Acknowledge the inactive state of an instance with this ID.

Example

Acknowledge list of active alarms synchronously:

Copy code

```
vector<AlarmAttributes> g_vecAlarmList;

void AcknowledgeAlarmSync(IRuntimePtr pRuntime)
{
    ICfUnknownPtr pUnk;
    pRuntime->GetObject(CCfString(L"Alarm"), &pUnk);

      IAlarmPtr pAlarm(pUnk);
      pAlarm->SetName("Tag1:Alarm1");
      CFRESULT errCode = pAlarm->Acknowledge();
    }
}
```

IAlarmResult (Page 8046)

IAlarmCallback

Description

The C++ interface "IAlarmCallback" defines methods for implementing asynchronous operations for monitoring active alarms. The methods are used by the "IAlarmSubscription" interface.

Members

The following methods are specified in the "IAlarmCallback" interface:

"OnAlarm" method

Callback method is called when active alarms on monitored systems change the alarm state.

The "OnAlarm" callback method is called when the "IAlarmSubscription.Start" method is used.

```
CFRESULT OnAlarm(
         IAlarmResultEnumerator* pItems,
         uint32_t systemError,
         CFSTR systemName,
         CFBOOL completed)
```

- `pItems`
  [in]: Points to an "IAlarmResultEnumerator" object that contains the enumeration of the changed active alarms.
- `systemError`
  [in]: Error code for the asynchronous operation

- `systemName`
  [in]: System of the associated Runtime system.
- `completed`
  [in]: True, if no more data from the callback can be expected.

"OnPendingAlarmsComplete" method

Callback method is called to display the completion of the handling of all the active alarms of a system.

The "OnPendingAlarmsComplete" callback method is called when the "IAlarmSubscription.Start" method is used.

```
CFRESULT OnPendingAlarmsComplete()
```

Example

In the following section, monitored active alarms are written asynchronously into the "g_vecAlarmList" map at a change. To this purpose the "SubscribeAlarm" function uses a "CAlarmValue" object that implements the "IAlarmCallback" interface and that uses the "COdkTagSourceCBBase" class. The service life of the "CAlarmValue" object is determined via reference counting.

Copy code

```
const uint32_t g_nMaxWaitTime = 6000;
vector<AlarmAttributes> g_vecAlarmList;

void SubscribeAlarm(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"AlarmSubscription"), &pUnk));
   IAlarmSubscriptionPtr pAlarm(pUnk);
   CAlarmValue* pAlarmValue = new CAlarmValue();
   pAlarmValue->AddRef();
   IAlarmCallback* pCB = pAlarmValue;
   CCfSafeArrayBound bounds(1UL, 0);
   CCfSafeArray daAttribute;
   CCfSafeArray daSystemID(CF_VT_SREF, 1, &bounds);
   CCfVariant daDataSource = 0;
   CCfVariant vSystemIDs = 0;
   // Subscription filter is currently not supported!
   CCfSmartString daFilter = L"";
   CCfSREF id(L"SYSTEM1");
   int32_t index = 0;
   daSystemID.PutElement(&index, &id);
   CCfVariant daLanguage = 1033;

   daSystemID.Detach(&vSystemIDs);
   CCfSmartString strFilter = L"";
   // Start Subscription
   pAlarm->SetFilter(strFilter.AllocCFSTR());
   pAlarm->SetLanguage(1033);
   pAlarm->SetSystemNames(vSystemIDs);
   Alarm->Start(pCB);
   // Wait for alarm notifications
   pAlarmValue->WaitForcompletion(g_nMaxWaitTime);
   Alarm->Stop();
   pAlarmValue->GetAlarmAttributes(g_vecAlarmList);
}
```

IAlarmSubscription (Page 8077)

IAlarmSourceCommandCallback

Description

The C++ interface "IAlarmSourceCommandCallback" defines methods for implementing asynchronous operations with active alarms. The methods are used by the "IAlarmSet" interface.

Members

The following methods are specified in the interface:

"OnAcknowledge" method

Callback method is called when an active alarm has been acknowledged.

The "OnAcknowledge" callback method is called when the "IAlarmSet.Acknowledge" method is used.

```
CFRESULT OnAcknowledge(
         CFRESULT SystemError,
         IAlarmSetResultEnumerator *AlarmSetResult,
         CFBOOL MoreFollows)
```

- `SystemError`
  [in]: Basic errors that occurred during the asynchronous transfer.
- `AlarmSetResult`
  [in]: Points to an enumeration with the alarms of the callback
- `MoreFollows`
  [in]: Status of the asynchronous transfer:
  - True: Further callbacks are to be expected.
  - False: This is the last callback.

"OnReset" method

Callback method is called when an active alarm has been removed.

The "OnReset" callback method is called when the "IAlarmSet.Reset" method is used.

```
CFRESULT OnReset(
         CFRESULT SystemError,
         IAlarmSetResultEnumerator *AlarmSetResult,
         CFBOOL MoreFollows)
```

- `SystemError`
  [in]: Basic errors that occurred during the asynchronous transfer.
- `AlarmSetResult`
  [in]: Points to an enumeration with the alarms of the callback
- `MoreFollows`
  [in]: Status of the asynchronous transfer:
  - True: Further callbacks are to be expected.
  - False: This is the last callback.

"OnDisable" method

Callback method is called when the generation of the alarm in the alarm source has been deactivated.

The "OnDisable" callback method is called when the "IAlarmSet.Disable" method is used.

```
CFRESULT OnDisable(
         CFRESULT SystemError,
         IAlarmSetResultEnumerator *AlarmSetResult,
         CFBOOL MoreFollows)
```

- `SystemError`
  [in]: Basic errors that occurred during the asynchronous transfer.
- `AlarmSetResult`
  [in]: Points to an enumeration with the alarms of the callback
- `MoreFollows`
  [in]: Status of the asynchronous transfer:
  - True: Further callbacks are to be expected.
  - False: This is the last callback.

"OnEnable" method

Callback method is called when the generation of the alarm in the alarm source has been activated again.

The "OnEnable" callback method is called when the "IAlarmSet.Enable" method is used.

```
CFRESULT OnEnable(
         CFRESULT SystemError,
         IAlarmSetResultEnumerator *AlarmSetResult,
         CFBOOL MoreFollows)
```

- `SystemError`
  [in]: Basic errors that occurred during the asynchronous transfer.
- `AlarmSetResult`
  [in]: Points to an enumeration with the alarms of the callback
- `MoreFollows`
  [in]: Status of the asynchronous transfer:
  - True: Further callbacks are to be expected.
  - False: This is the last callback.

"OnShelve" method

Callback method is called when an active alarm has been hidden.

The "OnShelve" callback method is called when the "IAlarmSet.Shelve" method is used.

```
CFRESULT OnShelve(
         CFRESULT SystemError,
```

```
        IAlarmSetResultEnumerator *AlarmSetResult,
        CFBOOL MoreFollows)
```

- `SystemError`
  [in]: Basic errors that occurred during the asynchronous transfer.
- `AlarmSetResult`
  [in]: Points to an enumeration with the alarms of the callback
- `MoreFollows`
  [in]: Status of the asynchronous transfer:
  - True: Further callbacks are to be expected.
  - False: This is the last callback.

"OnUnShelve" method

Callback method is called when an active alarm has been shown.

The "OnUnshelve" callback method is called when the "IAlarmSet.Unshelve" method is used.

```
CFRESULT OnUnshelve(
         CFRESULT SystemError,
        IAlarmSetResultEnumerator *AlarmSetResult,
         CFBOOL MoreFollows)
```

- `SystemError`
  [in]: Basic errors that occurred during the asynchronous transfer.
- `AlarmSetResult`
  [in]: Points to an enumeration with the alarms of the callback
- `MoreFollows`
  [in]: Status of the asynchronous transfer:
  - True: Further callbacks are to be expected.
  - False: This is the last callback.

Example

In the following section, monitored active alarms of the "g_vecAlarmList" vector are acknowledged asynchronously. To this purpose the "AcknowledgeAlarmAsync" function uses a "CAlarmSourceCommandCB" object that implements the "IAlarmSourceCommandCallback" interface and that uses the "COdkTagSourceCBBase" class. The service life of the "CAlarmSourceCommandCB" object is determined via reference counting.

Copy code

```
const uint32_t g_nMaxWaitTime = 6000;
vector<AlarmAttributes> g_vecAlarmList;

void AcknowledgeAlarmAsync(IRuntimePtr pRuntime)
{

    ICfUnknownPtr pUnk;
    CFRESULT errCode;
    if (CF_SUCCEEDED(pRuntime->GetObject(CCfString(L"AlarmSet"), &pUnk)))
    {
      IAlarmSetPtr pAlarmSet(pUnk);
      CAlarmSourceCommandCB* pAlarmSoureCommand = new CAlarmSourceCommandCB();
      pAlarmSoureCommand->AddRef();
      IAlarmSourceCommandCallback* pCB = pAlarmSoureCommand;
     vector<AlarmAttributes>::iterator it = g_vecAlarmList.begin();     // iterate through
list of notified alarms and acknowledge each alarm
      while (it != g_vecAlarmList.end())
      {
        IAlarm* pAlarm = nullptr;  CCfVariant vtAlarmName = it->m_strName;
        errCode = pAlarmSet->Add(vtAlarmName, &pAlarm);
        it++;
      }

      // acknowledged the AlarmSet
      errCode = pAlarmSet->Acknowledge(pCB);
      // wait for acknowledge callback
     if (CF_SUCCEEDED(errCode) && pAlarmSoureCommand->WaitForcompletion(g_nMaxWaitTime) ==
CF_SUCCESS)
      {
        ...
      }
    }
}
```

IAlarmSet (Page 8065)

IAlarmSet

Description

The C++ interface "IAlarmSet" specifies properties and methods for optimized access to several active alarms of the runtime system.

After the initialization of the "IAlarmSet" object, you can execute asynchronous operations with multiple alarms in one call, e. g. acknowledgment or comment. Simultaneous access demonstrates better performance and lower communication load than single access to multiple tags.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

The following methods are specified in the interface:

"GetCount" method

Return number of alarms of an AlarmSet list.

```
CFRESULT GetCount(uint32_t *value)
```

`value`
[out]: Points to the value for the number of alarms of the AlarmSet list.

"Remove" method

Remove a single alarm or an instance of an alarm from an AlarmSet.

```
CFRESULT Remove(CFSTR name, uint32_t instanceId)
```

- `name`
  [in]: Name of the alarm that is removed to the AlarmSet.
- `instanceId`
  [in]:
  Value = "0": Remove all instances of an active alarm.
  Value > "0": Remove instance with this ID.

"Add" method

Add an active alarm or an instance of the alarm to an AlarmSet.

```
CFRESULT Add(
         CFVARIANT p_varName,
         IAlarm** pAlarm,
         uint32_t instanceId)
```

- `p_varName`
  [in]: Name of the alarm tag that is added to the AlarmSet.
- `pAlarm`
  [out]: Points to the added "IAlarm" object of the AlarmSet.
- `instanceId`
  [in]:
  Value = "0": Add all instances of an active alarm.
  Value > "0": Add instance with this ID.

"Get" method

Reference an alarm or an instance of an alarm from an AlarmSet.

```
CFRESULT Get(
         const CFSTR p_varName,
         IAlarm** pAlarm,
         uint32_t instanceId)
```

- `p_varName`
  [in]: Name of the alarm tag.
- `pAlarm`
  [out]: Points to the "IAlarm" object of the AlarmSet.
- `instanceId`
  [in]:
  Value = "0": Reference all instances of an active alarm.
  Value > "0": Reference instance with this ID.

"Disable" method

Deactivate generation of alarms of the AlarmSet in the alarm source asynchronously.

```
CFRESULT Disable(IAlarmSourceCommandCallback* p_pCallback)
```

`p_pCallback`
[in/out]: Points to an "IAlarmSourceCommandCallback" object that implements the asynchronous operation.

"Enable" method

Activate generation of alarms of the AlarmSet in the alarm source again asynchronously.

```
CFRESULT Enable(IAlarmSourceCommandCallback* p_pCallback)
```

`p_pCallback`
[in/out]: Points to an "IAlarmSourceCommandCallback" object that implements the asynchronous operation.

"Shelve" method

Hide alarms of the AlarmSet asynchronously.

```
CFRESULT Shelve(IAlarmSourceCommandCallback* p_pCallback)
```

`p_pCallback`
[in/out]: Points to an "IAlarmSourceCommandCallback" object that implements the asynchronous operation.

"Unshelve" method

Show hidden alarms of the AlarmSet asynchronously again.

```
CFRESULT Unshelve(IAlarmSourceCommandCallback* p_pCallback)
```

`p_pCallback`
[in/out]: Points to an "IAlarmSourceCommandCallback" object that implements the asynchronous operation.

"Acknowledge" method

Acknowledge alarms of the AlarmSet asynchronously.

```
CFRESULT Acknowledge(IAlarmSourceCommandCallback* p_pCallback)
```

`p_pCallback`
[in/out]: Points to an "IAlarmSourceCommandCallback" object that implements the asynchronous operation.

"Reset" method

Acknowledge inactive state of the alarms of the AlarmSet asynchronously. This method is relevant for alarms with the state machine "Alarm with acknowledgment and confirmation". Other state machines do not require a reset.

```
CFRESULT Reset(IAlarmSourceCommandCallback* p_pCallback)
```

`p_pCallback`
[in/out]: Points to an "IAlarmSourceCommandCallback" object that implements the asynchronous operation.

"Clear" method

Remove all alarms from AlarmSets.

```
CFRESULT Clear()
```

Example

Reset of alarms in an alarm list. Reset is the acknowledgment of the inactive status.

Copy code

```
const uint32_t g_nMaxWaitTime = 6000;
vector<AlarmAttributes> g_vecAlarmList;
void ResetAlarmAsync(IRuntimePtr pRuntime)
{
  ICfUnknownPtr pUnk;
  CFRESULT errCode;
  if (CF_SUCCEEDED(pRuntime->GetObject(CCfString(L"AlarmSet"), &pUnk)))
  {
    IAlarmSetPtr pAlarmSet(pUnk);
    CAlarmSourceCommandCB* pAlarmSoureCommond = new CAlarmSourceCommandCB();
    pAlarmSoureCommond->AddRef();
    IAlarmSourceCommandCallback* pCB = pAlarmSoureCommond;
    vector<AlarmAttributes>::iterator it = g_vecAlarmList.begin();     // iterate through
list of notified alarms and reset each alarm
    while (it != g_vecAlarmList.end())
    {
      IAlarm* palarm = nullptr;
      CCfVariant vtAlarmName = it->m_strName;
      errCode = pAlarmSet->Add(vtAlarmName, &palarm);
      it++;
    }
    // Reset the AlarmSet
    errCode = pAlarmSet->Reset(pCB);
    //Check if an alarm could not be reset
    if (CF_SUCCEEDED(errCode) && pAlarmSoureCommond->WaitForcompletion(g_nMaxWaitTime) ==
CF_SUCCESS)
    {
      ...
    }
  }
}
```

IAlarmSetResult (Page 8069)

IAlarmSetResultEnumerator (Page 8070)

IAlarmSetResult

Description

The C++ interface "IAlarmSetResult" specifies methods for accessing properties of monitored alarms in AlarmSets.

All the methods return CF_SUCCESS following successful execution.

Members

The following methods are specified in the interface:

"GetSystemName" method

Return system name of the runtime system of an alarm in the AlarmSet.

```
CFRESULT GetSystemName(CFSTR *value)
```

`value`
[out]: Points to the associated system name.

"GetName" method

Return name of an alarm in the AlarmSet.

```
CFRESULT GetName(CFSTR *value)
```

`value`
[out]: Points to the name of an alarm

"GetInstanceID" method

Return InstanceID of an alarm in the AlarmSet.

```
CFRESULT GetInstanceID(uint32_t *value)
```

`value`
[out]: Points to the InstanceID of an alarm

"GetErrorCode" method

Return error code of an alarm in the AlarmSet.

```
CFRESULT GetErrorCode(uint32_t *value)
```

`value`
[out]: Points to the error code of an alarm.

IAlarmSet (Page 8065)

IAlarmSetResultEnumerator (Page 8070)

IAlarmSubscription (Page 8077)

IAlarmSetResultEnumerator

Description

The "IAlarmSetResultEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of monitored alarms of the runtime system.

All the methods return CF_SUCCESS following successful execution.

Members

The following methods are specified in the interface:

"Current" method

Output the current element of the enumeration of a list.

```
CFRESULT Current(IAlarmSetResult **ppItem)
```

`ppItem`
[out]: Points to the current "IAlarmSetResult" object as an element of the list.

"MoveNext" method

Go to the next element of the enumeration of a list.

```
CFRESULT MoveNext()
```

"Reset" method

Reset the current position in the enumeration of a list.

```
CFRESULT Reset()
```

The "MoveNext" method moves afterwards to the first element of the list.

"Count" method

Output the size of the enumeration or the number of elements of a list.

```
CFRESULT Count(uint32_t *value)
```

`value`
[out]: Points to the value for the number of elements of the list.

IAlarmSet (Page 8065)

IAlarmSetResult (Page 8069)

IAlarmTrigger

Description

The C++ interface "AlarmTrigger" specifies methods for triggering alarms.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

"CreateSystemAlarm" method

Creates an alarm of the SystemAlarmWithoutClearEvent class with the state machine alarm without "Inactive with acknowledgment" status.

```
CFRESULT CreateSystemAlarm(
CFVARIANT alarmText,
CFSTR area,
CFVARIANT p_AlarmParameterValue1,
CFVARIANT p_AlarmParameterValue2,
CFVARIANT p_AlarmParameterValue3,
CFVARIANT p_AlarmParameterValue4,
CFVARIANT p_AlarmParameterValue5,
CFVARIANT p_AlarmParameterValue6,
CFVARIANT p_AlarmParameterValue7)
```

- `alarmText`
  [in]: The alarm text. You have the following options:
  - Transfer a text list of type "ITextList".
    The list entries of the text list can contain the multilingual text or references to other text lists.

    Note

    Only user-defined text lists

    This method processes only user-defined text lists.

  - Transfer static string with monolingual text.
- `area`
  [in]: The area of origin of the alarm
- `p_AlarmParameterValue`<Number>
  [in]: User-defined comments

The alarm triggers an event with the following event path:

- For multilingual alarm texts:
  `@ScriptingSystemEvents.SystemAlarmWithoutClearEvent:SystemAlarmWithoutClearEvent`
- For monolingual alarm text:
  `@ScriptingSystemEvents.SystemAlarmWithoutClearEventText:SystemAlarmWithoutClearEvent`

"CreateSystemInformation" method

Creates an alarm of the SystemInformation class with the state machine alarm without "Inactive without acknowledgment" status.

```
CFRESULT CreateSystemInformation(
CFVARIANT alarmText,
CFSTR area,
CFVARIANT p_AlarmParameterValue1,
CFVARIANT p_AlarmParameterValue2,
CFVARIANT p_AlarmParameterValue3,
CFVARIANT p_AlarmParameterValue4,
CFVARIANT p_AlarmParameterValue5,
```

```
CFVARIANT p_AlarmParameterValue6,
CFVARIANT p_AlarmParameterValue7)
```

- `alarmText`
  [in]: The alarm text. You have the following options:
  - Transfer a text list of the type "ITextList".
    The list entries of the text list can directly contain multilingual alarm texts or references to other text lists with multilingual alarm texts.

    Note

    Only user-defined text lists

    This method processes only user-defined text lists.

  - Transfer static string with monolingual text.
- `area`
  [in]: The area of origin of the alarm
- `p_AlarmParameterValue`<Number>
  [in]: User-defined comments

The alarm triggers an event with the following event path:

- For multilingual alarm texts: `@ScriptingSystemEvents.SystemInformation:SystemInformation`
- For monolingual alarm text: `@ScriptingSystemEvents.SystemInformationText:SystemInformation`

"CreateOperatorInputInformation" method

Creates an alarm of the OperatorInputInformation class with the state machine alarm without "Inactive without acknowledgment" status.

```
CFRESULT CreateOperatorInputInformation(
CFVARIANT alarmText,
CFSTR area,
CFVARIANT p_AlarmParameterValue1,
CFVARIANT p_AlarmParameterValue2,
CFVARIANT p_AlarmParameterValue3,
CFVARIANT p_AlarmParameterValue4,
CFVARIANT p_AlarmParameterValue5,
```

```
CFVARIANT p_AlarmParameterValue6,
CFVARIANT p_AlarmParameterValue7)
```

- `alarmText`
  [in]: The alarm text. You have the following options:
  - Transfer a text list of the type "ITextList".
    The list entries of the text list can directly contain multilingual alarm texts or references to other text lists with multilingual alarm texts.

    Note

    Only user-defined text lists

    This method processes only user-defined text lists.

  - Transfer static string with monolingual text.
- `area`
  [in]: The area of origin of the alarm
- `p_AlarmParameterValue`<Number>
  [in]: User-defined comments

The alarm triggers an event with the following event path:

- For multilingual alarm texts:
  `@ScriptingSystemEvents.OperatorInputInformation:OperatorInputInformation`
- For monolingual alarm text:
  `@ScriptingSystemEvents.OperatorInputInformationText:OperatorInputInformation`

Example

The following code examples show how to trigger alarms of the class SystemAlarmWithoutClearEvent. Alarms of the classes SystemInformation and OperatorInputInformation are triggered in the same way.

Copying code

```
void CreateSystemAlarm(IRuntimePtr pRuntime)
{
  ICfUnknownPtr pUnk;
  if (CF_SUCCEEDED(pRuntime->GetObject(CCfString(L"AlarmTrigger"), &pUnk)))
  {
    IAlarmTriggerPtr pTrigger(pUnk);
    if (pTrigger != nullptr)
    {
      pTrigger->CreateSystemAlarm(CCfVariant(L"Alarm Text"), CCfString(L"Alarm Area"),
CCfVariant(L"param1"), CCfVariant(L"param2"), CCfVariant(L"param3"),
CCfVariant(L"param4"), CCfVariant(L"param5"), CCfVariant("param6"), CCfVariant("param7"));
    }
  }
}
```

An alarm with multilingual text is created in the following code sample. The alarm text is retrieved from a text list. The alarm text contains a dynamic value (@1%d@), which is transferred via associated value 1.

Copy code

```
void CreateSystemAlarmWithAlarmTextAsTextList(IRuntimePtr pRuntime)
{
  ICfUnknownPtr pUnk;
  if (CF_SUCCEEDED(pRuntime->GetObject(CCfString(L"AlarmTrigger"), &pUnk)))
  {
    IAlarmTriggerPtr pTrigger(pUnk);
    if (pTrigger != nullptr)
    {
      if (CF_SUCCEEDED(pRuntime->GetObject(CCfString("TextList"), &pUnk)))
      {
        ITextListPtr ptextList(pUnk);
        if (nullptr != ptextList)
        {
          // Text list: MyTextList
          // Test list entry index: 101
          // Text: "My input msg. input value = @1%d@"
          ptextList->SetName(CCfString(L"MyTextList"));
          ptextList->SetTextListEntryIndex(101);
          pTrigger->CreateSystemAlarm(CCfVariant(ptextList), CCfString(L"Alarm Area"),
CCfVariant(L"125"),// dynamic value for format specifier @1%d@;
              CCfVariant(), CCfVariant(), CCfVariant(), CCfVariant(), CCfVariant(),
CCfVariant());
        }
      }
    }
  }
}
```

An alarm with multilingual text is created in the following code sample. The alarm text is retrieved from a text list. In turn, the alarm text contains a reference to a second text list and

a dynamic value (@3%s@), which is transferred via associated value 3. (Use case: Nested text list)

Copy code

```
void CreateSystemAlarmWithTextListAsParameterValue(IRuntimePtr pRuntime)
{
  ICfUnknownPtr pUnk;
  if (CF_SUCCEEDED(pRuntime->GetObject(CCfString(L"AlarmTrigger"), &pUnk)))
  {
    IAlarmTriggerPtr pTrigger(pUnk);
    if (pTrigger != nullptr)
    {
      ICfUnknownPtr pUnktextList, pUnktextList1;
      if (CF_SUCCEEDED(pRuntime->GetObject(CCfString("TextList"), &pUnktextList)) &&
CF_SUCCEEDED(pRuntime->GetObject(CCfString("TextList"), &pUnktextList1)))
      {
        ITextListPtr pTextList_1(pUnktextList);
        if (nullptr != pTextList_1)
        {
          pTextList_1->SetName(CCfString(L"Text_List_1"));
          pTextList_1->SetTextListEntryIndex(1); //Text with reference to Text_List_2:
@1%t#2T@ Val: @3%s@
        }
        ITextListPtr pTextList_2(pUnktextList1);
        if (nullptr != pTextList_2)
        {
          pTextList_2->SetName(CCfString(L"Text_List_2"));
        }
        pTrigger->CreateSystemAlarm(CCfVariant(pTextList_1), CCfString(L"Alarm Area"),
CCfVariant(1), // Index for Text_list_2
            CCfVariant(pTextList_2), // Text_list_2 object
            CCfVariant(L"Hello"), // Dynamic value of @3%s@
            CCfVariant(), CCfVariant(), CCfVariant(), CCfVariant());
      }
    }
  }
}
```

ITextList

Description

The C++ interface "ITextList" is used to transfer multilingual alarm texts for system alarms and operator input alarms. See section IAlarmTrigger (Page 8071), CreateSystemInformation method. An ITextList instance is passed to the alarm text. When the operator input alarm is generated, it is replaced by the configured text from the text list.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

"GetName" method

Returns the name of the text list.

```
GetName(CFSTR* name)
```

- `name`:
  [out]: The name

"SetName" method

Set the name of the text list.

```
SetName(CFSTR name)
```

- `name`:
  [in]: The name

"GetTextListEntryIndex" method

Return the index of the list entry.

```
GetTextListEntryIndex)(OUT uint32_t* pIndex)
```

- `pIndex`
  [out]: The index

"SetTextListEntryIndex" method

Set the index of the list entry.

```
SetTextListEntryIndex)(IN uint32_t pIndex)
```

- `pIndex`
  [in]: The index

IAlarmSubscription

Description

The C++ interface "IAlarmSubscription" specifies methods for monitoring tags of the Runtime system. The subscribed tags are monitored for a change of the alarm state.

Members

The following methods are specified in the interface:

"Start" method

Start monitoring of active alarms.

```
CFRESULT Start(IAlarmCallback* callbackPtr)
```

`callbackPtr`
[in/out]: Points to an "IAlarmCallback" object that implements the asynchronous monitoring.

"Stop" method

Stop monitoring of active alarms.

Note

Start and Stop in Windows Forms applications

Do not call the "Stop" method for a Windows Forms application in the same thread where you called "Start".

```
CFRESULT Stop()
```

"SetSystemNames" method

Set system names of runtime systems for the monitoring of active alarms.

```
CFRESULT SetSystemNames(CFVARIANT systemIDs)
```

`systemIDs`
[in]: System names of Runtime systems

"GetSystemNames" method

Read out system names of runtime systems for the monitoring of active alarms.

```
CFRESULT GetSystemNames(CFVARIANT* systemIDs)
```

`systemIDs`
[out]: Points to system names of Runtime systems.

"SetLanguage" method

Set country identification of the language for monitored alarms.

```
CFRESULT SetLanguage(uint32_t language)
```

`language`
[in]: Country identification of the language

"GetLanguage" method

Read out country identification of the language for monitored alarms.

```
CFRESULT GetLanguage(uint32_t* language)
```

`language`
[out]: Points to country identification of the language.

"GetFilter" method

Supplies the string by which the result set is filtered.

```
CFRESULT GetFilter(CFSTR* filter)
```

- `filter`
  [out]: SQL-type string for filtering the result set of active alarms.

"SetFilter" method

Sets the string for filtering the result set of active alarms.

```
CFRESULT SetFilter(IN CFSTR filter)
```

- `filter`
  [in]: SQL-type string for filtering the result set of active alarms.
  All properties of an alarm can be used in the filter string. The filter string can contain operators. Refer to the section Syntax of the alarm filter (Page 7828).

Example

In the following section, monitored active alarms are written asynchronously into the "g_vecAlarmList" map at a change. To this purpose the "SubscribeAlarm" function uses a "CAlarmValue" object that implements the "IAlarmCallback" interface and that uses the "COdkTagSourceCBBase" class. The service life of the "CAlarmValue" object is determined via reference counting.

Copy code

```
const uint32_t g_nMaxWaitTime = 6000;
vector<AlarmAttributes> g_vecAlarmList;

void SubscribeAlarm(IRuntimePtr pRuntime)
{
    ICfUnknownPtr pUnk;
    pRuntime->GetObject(CCfString(L"AlarmSubscription"), &pUnk);

    IAlarmSubscriptionPtr pAlarm(pUnk);
    CAlarmValue* pAlarmValue = new CAlarmValue();
    pAlarmValue->AddRef();
    IAlarmCallback *pCB = pAlarmValue;

    CCfSafeArrayBound bounds(1UL, 0);

    CCfSafeArray daAttribute;
    CCfSafeArray daSystemID(CF_VT_SREF, 1, &bounds);
    CCfVariant daDataSource = 0;
    CCfVariant vSystemIDs = 0;

    CCfSmartString daFilter = L"";

    CCfSREF id(L"SYSTEM1");
    int32_t index = 0;
    daSystemID.PutElement(&index, &id);

    CCfVariant daLanguage = 1033;

    daSystemID.Detach(&vSystemIDs);

    CCfSmartString strFilter = L"";
    // Start Subscription
    pAlarm->SetFilter(strFilter.AllocCFSTR());
    pAlarm->SetLanguage(1033);
    pAlarm->SetSystemNames(vSystemIDs);

    pAlarm->Start(pCB);

    // Wait for alarm notifications
    if (pAlarmValue->WaitForcompletion(g_nMaxWaitTime) == CF_SUCCESS)
    {
       pAlarm->Stop();
       // Get current alarms from callback
       pAlarmValue->GetAlarmAttributes(g_vecAlarmList);
    }
}
```

IAlarmResult (Page 8046)

IAlarmCallback (Page 8059)

IAlarmSetResult (Page 8069)

ILoggedAlarmResult

Description

The C++ interface "ILoggedAlarmResult" specifies methods for accessing properties of logged alarms of a logging system.

An "ILoggedAlarmResult" object is a pure data object that maps all properties of a logged alarm.

Members

The following methods are specified in the interface:

"GetInstanceID" method

Return InstanceID of a logged alarm.

```
CFRESULT GetInstanceID(uint32_t *value)
```

`value`
[out]: Points to the InstanceID of the logged alarm.

"GetName" method

Return the name of the logged alarm.

```
CFRESULT GetName(CFSTR *value)
```

`value`
[out]: Points to the name of the logged alarm.

"GetAlarmClassName" method

Return the name of the alarm class.

```
CFRESULT GetAlarmClassName(CFSTR *value)
```

`value`
[out]: Points to the symbol of the alarm class of the logged alarm.

"GetAlarmClassSymbol" method

Return the symbol of the alarm class.

```
CFRESULT GetAlarmClassSymbol(CFSTR *value)
```

`value`
[out]: Points to the name of the alarm class of the logged alarm.

"GetState" method

Return alarm state of the logged alarm.

```
CFRESULT GetState(int32_t* *value)
```

`value`
[out]: Points to the alarm state.

"GetStateText" method

Return alarm state of the logged alarm as text, for example, "active" or "inactive".

```
CFRESULT GetStateText(CFSTR *value)
```

`value`
[out]: Points to the alarm state as text.

"GetEventText" method

Return text that describes the alarm event of the logged alarm.

```
CFRESULT GetEventText(CFSTR *value)
```

`value`
[out]: Points to the text that describes the alarm event.

"GetAlarmText1GetAlarmText9" method

Return additional texts 1-9 of the logged alarm.

```
CFRESULT GetAlarmText1(CFSTR *value)
```

...

```
CFRESULT GetAlarmText9(CFSTR *value)
```

`value`
[out]: Points to the additional text of the logged alarm.

"GetTextColor" method

Return text color of the alarm state of the logged alarm.

```
CFRESULT GetTextColor(uint32_t *value)
```

`value`
[out]: Points to the text color of the alarm state.

"GetBackColor" method

Return background color of the alarm state of the logged alarm.

```
CFRESULT GetBackColor(uint32_t *value)
```

`value`
[out]: Points to the background color of the alarm state.

"GetFlashing" method

Return flashing background color of the alarm state of the logged alarm.

```
CFRESULT GetFlashing(CFBOOL *value)
```

`value`
[out]: Points to the flashing background color of the alarm state.

"GetModificationTime" method

Return time of the last modification to the alarm state of the logged alarm.

```
CFRESULT GetModificationTime(CFDATETIME64 *value)
```

`value`
[out]: Points to the time of the last change of the alarm state.

"GetChangeReason" method

Return trigger event for modification of the alarm state of the logged alarm.

```
CFRESULT GetChangeReason(uint16_t *value)
```

`value`
[out]: Points to the trigger event for the change of the alarm state.

"GetRaiseTime" method

Return trigger time of the logged alarm.

```
CFRESULT GetRaiseTime(CFDATETIME64 *value)
```

`value`
[out]: Points to the time the logged alarm was triggered.

"GetAcknowledgementTime" method

Return time of alarm acknowledgment of the logged alarm.

```
CFRESULT GetAcknowledgementTime(CFDATETIME64 *value)
```

`value`
[out]: Points to the time of acknowledgment of the logged alarm.

"GetClearTime" method

Return time of reset of the logged alarm.

```
CFRESULT GetClearTime(CFDATETIME64 *value)
```

`value`
[out]: Points to the time when the logged alarm is reset.

"GetResetTime" method

Return time of reset of the logged alarm.

```
CFRESULT GetResetTime(CFDATETIME64 *value)
```

`value`
[out]: Points to the time of the reset of the logged alarm.

"GetSuppressionState" method

Return status of visibility of the logged alarm.

```
CFRESULT GetSuppressionState(uint8_t *value)
```

`value`
[out]: Points to the status of the visibility of the logged alarm.

"GetPriority" method

Return relevance for display and sorting of the logged alarm.

```
CFRESULT GetPriority(uint8_t *value)
```

`value`
[out]: Points to the relevance of the logged alarm.

"GetOrigin" method

Return origin for display and sorting of the logged alarm.

```
CFRESULT GetOrigin(CFSTR *value)
```

`value`
[out]: Points to the origin of the logged alarm.

"GetArea" method

Return origin area for display and sorting of the logged alarm.

```
CFRESULT GetArea(CFSTR *value)
```

`value`
[out]: Points to the origin area of the logged alarm.

"GetValue" method

Return process value of the logged alarm.

```
CFRESULT GetValue(CFVARIANT *value)
```

`value`
[out]: Points to the process value of the logged alarm.

"GetValueQuality" method

Return quality of the process value of the logged alarm.

```
CFRESULT GetValueQuality(uint16_t *value)
```

`value`
[out]: Points to the quality of the process value of the logged alarm.

"GetValueLimit" method

Return process value limit of the logged alarm.

```
CFRESULT GetValueLimit(CFVARIANT *value)
```

`value`
[out]: Points to the limit of the process value of the logged alarm.

"GetUserName" method

Return the user name of the logged operator input alarm.

```
CFRESULT GetUserName(CFSTR *value)
```

`value`
[out]: Points to the user name of the logged operator input alarm.

"GetLoopInAlarm" method

Return function that navigates from the alarm control to its origin.

```
CFRESULT GetLoopInAlarm(CFSTR *value)
```

`value`
[out]: Points to the function name that navigates to the origin of the logged alarm.

"GetAlarmParameterValues" method

Return parameter values of the logged alarm.

```
CFRESULT GetAlarmParameterValues(CFVARIANT *value)
```

`value`
[out]: Points to the parameter values of the logged alarm.

"GetInvalidFlags" method

Return identification of the logged alarm with invalid data.

```
CFRESULT GetInvalidFlags(uint8_t *value)
```

`value`
[out]: Points to the invalid data of the logged alarm.

"GetConnection" method

Return connection via which the logged alarm was triggered.

```
CFRESULT GetConnection CFSTR *value)
```

`value`
[out]: Points to the connection of the logged alarm.

"GetSystemSeverity" method

Return severity of the system error.

```
CFRESULT GetSystemSeverity(uint8_t *value)
```

`value`
[out]: Points to the severity of the system error.

"GetUserResponse" method

Return expected or required user response to the logged alarm.

```
CFRESULT GetUserResponse(uint8_t *value)
```

`value`
[out]: Points to the expected or required user response to the logged alarm.

"GetDeadBand" method

Return range of the triggering tag in which no alarms are generated.

```
CFRESULT GetDeadBand(CFVARIANT *value)
```

`value`
[out]: Points to the deadband of the logged alarm.

"GetHostName" method

Return the name of the host that triggered the alarm.

```
CFRESULT GetHostName(CFSTR *value)
```

`value`
[out]: Points to host name.

"GetInfoText" method

Return text for the alarm that contains the associated work instruction.

```
CFRESULT GetInfoText(CFSTR *value)
```

`value`
[out]: Points to the text of the operator instruction.

"GetStateMachine" method

Return StateMachine model of the alarm. The StateMachine represents the behavior of alarms through the arrangement of alarm states and alarm events, e.g. "RaiseClear", "RaiseRequiresAcknowledgment" or "RaiseClearOptionalAcknowledgment".

```
CFRESULT GetStateMachine(uint8_t *value)
```

`value`
[out]: Shows the model of the StateMachine of the logged alarm.

"GetSingleAcknowledgement" method

Returns whether an alarm may be acknowledged only individually or may be acknowledged as a group or multiple selection.

```
CFRESULT GetSingleAcknowledgement(CFBOOL *value)
```

`value`
[out]: Points to the acknowledgement specification.

"GetLoggedAlarmStateObjectID" method

Return ID of the alarm state for referencing within the logging system.

```
CFRESULT GetLoggedAlarmStateObjectID(CFSTR *value)
```

`value`
[out]: Points to the ID of the alarm state of the logged alarm.

"GetID" method

Return the user-defined ID of the alarm that is also used in the display.

```
CFRESULT GetID(uint32_t *value)
```

`value`
[out]: Points to the ID of the logged alarm.

"GetSourceType" method

Return source from which the alarm was generated, for example, tag-based, controller-based or system-based alarm.

```
CFRESULT GetSourceType(uint16_t *value)
```

`value`
[out]: Points to the type of source of the logged alarm.

Method "GetDuration"

Returns the time interval in nanoseconds between triggering of the logged alarm and its previous status change.

```
CFRESULT GetDuration(CFTIMESPAN64 *value)
```

`value`
[out]: The time interval in nanoseconds

ILoggedAlarmResultEnumerator (Page 8087)

IAlarmLogging (Page 8088)

IAlarmLoggingSubscription (Page 8092)

ILoggedAlarmResultEnumerator

Description

The "ILoggedAlarmResultEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of logged alarms of a logging system. Through the enumeration, you access individual alarms from the set of logged alarm of a logging system.

All the methods return CF_SUCCESS following successful execution.

Members

The following methods are specified in the interface:

"Current" method

Output the current element of the enumeration of a list.

```
CFRESULT Current(ILoggedAlarmResult **ppItem)
```

`ppItem`
[out]: Points to the current "ILoggedAlarmResult" object as an element of the list.

"MoveNext" method

Go to the next element of the enumeration of a list.

```
CFRESULT MoveNext()
```

"Reset" method

Reset the current position in the enumeration of a list.

```
CFRESULT Reset()
```

The "MoveNext" method moves afterwards to the first element of the list.

"Count" method

Output the size of the enumeration or the number of elements of a list.

```
CFRESULT Count(uint32_t *value)
```

`value`
[out]: Points to the value for the number of elements of the list.

See also

ILoggedAlarmResult (Page 8081)

IAlarmLogging (Page 8088)

IAlarmLogging

Description

The C++ interface "IAlarmLogging" specifies methods for reading out logged alarms of a logging system.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

The following methods are specified in the interface:

"Read" method

Read out logged alarms of a time period synchronously from logging system.

```
CFRESULT Read(
         CFDATETIME64 begin,
         CFDATETIME64 end,
         CFSTR filter,
         uint32_t language,
         CFVARIANT systemIDs,
         ILoggedAlarmResultEnumerator **ppEnumerator)
```

- `begin`
  [in]: Start date of the time period
- `end`
  [in]: End date of the time period
- `filter`
  [in]: Filter for limiting the read operation with properties of the "ILoggedAlarmResult" object.

- `language`
  [in]: Country identification of the language of the logged alarm text
- `systemIDs`
  [in]: System names of the runtime systems of the logged alarms. Default: local system
- `ppEnumerator`
  [out]: Points to the logged alarms as an "ILoggedAlarmResultEnumerator" object.

"ReadAsync" method

Read out logged alarms of a time period asynchronously from logging system.

```
CFRESULT ReadAsync(
         CFDATETIME64 begin,
         CFDATETIME64 end,
         CFSTR filter,
         uint32_t language,
         CFVARIANT systemIDs,
         IAlarmLoggingCallback *pLoggedAlarmCb)
```

- `begin`
  [in]: Start date of the time period
- `end`
  [in]: End date of the time period
- `filter`
  [in]: Filter for limiting the read operation with properties of the "ILoggedAlarmResult" object.
- `language`
  [in]: Country identification of the language of the logged alarm text
- `systemIDs`
  [in]: System names of the runtime systems of the logged alarms. Default: local system
- `pLoggedAlarmCb`
  [in]: Points to the "IAlarmLoggingCallback" object that implements the callback interface.

Example

Read historical alarms synchronously from the logging system:

Copy code

```
void LoggingReadAlarmSync(IRuntimePtr pRuntime)
{
    ICfUnknownPtr pUnk;
    pRuntime->GetObject(CCfString(L"LoggedAlarm"), &pUnk);

    CCfVariant vSystemIDs = 0;
    CFSAFEARRAYBOUND* bounds = nullptr;
    CCfSafeArray daSystemID(CF_VT_SREF, 1, bounds);
    CCfSREF id(L"SYSTEM1");
    int32_t index = 0;
    daSystemID.PutElement(&index, &id);
    daSystemID.Detach(&vSystemIDs);

    IAlarmLoggingPtr pAlarm(pUnk);

    CCfDateTime64 begin, end;
    begin = CCfDateTime64::Now(true);
    end = begin;
    begin.SubtractTimeSpan(Get1Minute() * 3);

    ILoggedAlarmResultEnumeratorPtr pItems;
    // Read value of tag
    pAlarm->Read(begin, end, CCfString(""), 1033, vSystemIDs, &pItems);

    std::wcout << "Read finished " << std::endl;

    // Iterate over the process value objects and print them
    while (CF_SUCCEEDED(pItems->MoveNext()))
    {
        ILoggedAlarmResultPtr pValue;
        pItems->Current(&pValue); // get current process value
        CCfString timeStamp;
        CFDATETIME64 cfTimeStamp;
        pValue->GetModificationTime(&cfTimeStamp);
        CCfDateTime64 time(cfTimeStamp);
        timeStamp = time.GetDateTimeString(false);
        CCfString strName;
        pValue->GetName(&strName);
        CCfVariant varValue;
        pValue->GetValue(&varValue);
        std::wcout << strName.ToUTF8().c_str() << L" " << timeStamp.ToUTF8().c_str() << L"
Value: " << (double)(varValue) << std::endl;
    }
}
```

ILoggedAlarmResult (Page 8081)

ILoggedAlarmResultEnumerator (Page 8087)

IAlarmLoggingCallback

Description

The C++ interface "IAlarmLoggingCallback" defines methods for implementing asynchronous operations for monitoring active alarms. The methods are used by the "IAlarmLogging" and "IAlarmLoggingSubscription" interfaces.

All the methods return CF_SUCCESS after execution.

Members

The following methods are specified in the "IAlarmCallback" interface:

"OnReadComplete" method

Callback method is called on completion of asynchronous read operations in logging systems.

The "OnReadComplete" callback method is called when the "IAlarmLogging.ReadAsync" method is used.

```
CFRESULT OnReadComplete(ILoggedAlarmResultEnumerator *pEnumerator,
         uint32_t errorCode,
         int32_t contextId)
```

- `pEnumerator`
  [out]: Points to an "ILoggegAlarmResultEnumerator" object that contains the enumeration of the logged alarms.
- `errorCode`
  [out]: Error code for the asynchronous operation
- `contextId`
  [out]: ContextID as additional identification feature of the logged alarms.

"OnDataChanged" method

Callback method is called upon a change of a monitored alarm in logging systems.

The "OnDataChanged" callback method is called when the "IAlarmLoggingSubscription.Start" method is used.

```
CFRESULT OnDataChanged(ILoggedAlarmResultEnumerator *pEnumerator,
         uint32_t errorCode,
         int32_t contextId)
```

- `pEnumerator`
  [out]: Points to an "ILoggegAlarmResultEnumerator" object that contains the enumeration of the logged alarms.
- `errorCode`
  [out]: Error code for the asynchronous operation
- `contextId`
  [out]: ContextID as additional identification feature of the logged alarms.

IAlarmLogging (Page 8088)

IAlarmLoggingSubscription (Page 8092)

IAlarmLoggingSubscription

Description

The C++ interface "IAlarmLoggingSubscription" specifies methods for monitoring logged alarms of a logging system.

All the methods return CF_SUCCESS following successful execution. In the case of an error, the methods return the corresponding error code.

Members

The following methods are specified in the interface:

"SetFilter" method

Set SQL-type string for filtering the result set of the logged alarms.

```
CFRESULT SetFilter(CFSTR filter)
```

`filter`
[in]: Filter string for logged alarms

"SetLanguage" method

Set country identifier of the language for monitoring of logged alarms.

```
CFRESULT SetLanguage(uint32_t language)
```

`language`
[in]: Country identification of the language

"SetSystemName" method

Set system names of runtime systems for the monitoring of logged alarms.

```
CFRESULT SetSystemName(CFVARIANT systemIDs)
```

`systemIDs`
[in]: System name of Runtime systems

"Start" method

Start monitoring of logged alarms.

```
CFRESULT Start(IAlarmLoggingCallback* pLoggedAlarmCb)
```

- `filter`
  [in]: Filter for limiting the read operation with properties of the "ILoggedAlarmResult" object.
- `pLoggedAlramCb`
  [in/out]: Points to an "IAlarmLoggingCallback" object that implements asynchronous monitoring.

"Stop" method

Stop monitoring of all logged alarms.

```
CFRESULT Stop()
```

Example

Monitoring historical alarms. The values are returned by the "IAlarmLoggingCallback" object:

Copy code

```
void LoggingSubscribeAlarm(IRuntimePtr pRuntime)
{
    ICfUnknownPtr pUnk;
    pRuntime->GetObject(CCfString(L"LoggedAlarmSubscribtion"), &pUnk);

    CCfVariant vSystemIDs = 0;
    CFSAFEARRAYBOUND* bounds = nullptr;
    CCfSafeArray daSystemID(CF_VT_SREF, 1, bounds);
    CCfSREF id(L"SYSTEM1");
    int32_t index = 0;
    daSystemID.PutElement(&index, &id);
    daSystemID.Detach(&vSystemIDs);

    IAlarmLoggingSubscriptionPtr pAlarm(pUnk);
    pAlarm->SetSystemName(vSystemIDs);
    pAlarm->SetLanguage(1033);

    COdkAlarmLoggingCB* pAlarmCB = new COdkAlarmLoggingCB();

    pAlarmCB->AddRef();

    // subscribe tags
    pAlarm->Start(pAlarmCB);
}
```

20.3.9.5 Interfaces for connections

IConnectionResult

Description

The C++ interface "IConnectionResult" provides methods for access to the details of connections.

Members

The following methods are specified in the interface:

"GetName" method

Return name of the connection.

```
CFRESULT GetName(CFSTR *pName)
```

`pName`
[out]: Points to the name of the connection.

"GetConnectionState" method

Return status of the connection.

```
CFRESULT GetConnectionState(CFENUM *pConnectionState)
```

`pConnectionState`
[out]: Points to the enumeration, which can contain the following values:

- `Disabled` (0)
- `Connecting` (1)
- `Connected` (2)
- `Disconnecting` (3)
- `Disconnected` (4)
- `Reconnecting` (5)

"GetEstablishmentMode" method

Return mode in which the connection is established.

```
CFRESULT GetEstablishmentMode(CFENUM *pEstablishmentMode)
```

`pEstablishmentMode`
[out]: Points to the enumeration, which can contain the following values:

- `None` (0)
- `AutomaticActive` (1)
- `AutomaticPassive` (2)
- `OnDemandActive` (3)
- `OnDemandPassive` (4)

"GetTimeSynchronizationMode" method

Mode of time synchronization between HMI system and AS.

```
CFRESULT GetTimeSynchronizationMode(CFENUM
*pTimeSynchronizationMode)
```

`pTimeSynchronizationMode`
[out]: Points to the enumeration, which can contain the following values:

- `None` (0)
- `Subordinate` (1)
- `Lead` (2)

"GetDisabledAtStartup" method

Indicates whether the connection is disabled at the start of Runtime.

```
CFRESULT GetDisabledAtStartup(CFBOOL *pDisabledAtStartup)
```

`pDisabledAtStartup`
[out]: Points to a Boolean value.

"GetEnabled" method

Indicates whether the connection is active.

```
CFRESULT GetEnabled(CFBOOL *pEnabled)
```

`pbEnabled`
[out]: Points to a Boolean value.

"GetConnectionType" method

Return protocol of a communication driver, e.g. "S7 Classic".

```
CFRESULT GetConnectionType(CFSTR *pConnectionType)
```

`pConnectionType`
[out]: Points to the name of the protocol.

"GetError" method

Return error code of the connection.

```
CFRESULT GetError(uint32_t *pError)
```

`pError`
[out]: Points to the error code.

Example

Output connection details:

Copy code

```
void DisplayConnectionInfo(IConnectionResultPtr pConnectionresult,IRuntimePtr pRuntime)
{
   CCfString strName;
   pConnectionresult->GetName(&strName);
   std::cout << "ConnectionName:" << strName.ToUTF8() << std::endl;
   CCfString strConnectiontype;
   pConnectionresult->GetConnectionType(&strConnectiontype);
   std::cout << "ConnectionType:" << strConnectiontype.ToUTF8() << std::endl;
   CFENUM enConnectionState;
   pConnectionresult->GetConnectionState(&enConnectionState);
   HmiConnectionState enumconnectionState =
static_cast<HmiConnectionState>(enConnectionState);
   ConnectionState(enumconnectionState);
   CFENUM enEstablishmentMode;
   pConnectionresult->GetEstablishmentMode(&enEstablishmentMode);
   HmiConnectionEstablishmentMode enumEstablishmentMode =
static_cast<HmiConnectionEstablishmentMode>(enEstablishmentMode);
   Establishmentmode(enumEstablishmentMode);
   CFENUM enTimeSynchronizationMode;
   pConnectionresult->GetTimeSynchronizationMode(&enTimeSynchronizationMode);
   HmiTimeSynchronizationMode enumTimeSynchronizationMode =
static_cast<HmiTimeSynchronizationMode>(enTimeSynchronizationMode);
   TimeSynchronizationmode(enumTimeSynchronizationMode);
   CFBOOL bDisableatStartup;
   pConnectionresult->GetDisabledAtStartup(&bDisableatStartup);
   std::cout << "DisableStartup:" << (int)bDisableatStartup << std::endl;
   CFBOOL bEnabled;
   pConnectionresult->GetEnabled(&bEnabled);
   std::cout << "Enabled:" << (int)bEnabled << std::endl;
}
```

IConnection (Page 8101)

IConnectionResultEnumerator (Page 8096)

IConnectionResultEnumerator

Description

The "IConnectionResultEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of connection details of the Runtime system. The enumeration is used, for example, when reading out connections of a connection set.

All the methods return CF_SUCCESS following successful execution.

Members

The following methods are specified in the interface:

"Current" method

Output the current element of the enumeration of a list.

```
CFRESULT Current(IConnectionResult **ppItem)
```

ppItem
[out]: Points to the current "IConnectionResult" object as an element of the list.

"MoveNext" method

Go to the next element of the enumeration of a list.

```
CFRESULT MoveNext()
```

"Reset" method

Reset the current position in the enumeration of a list.

```
CFRESULT Reset()
```

The "MoveNext" method moves afterwards to the first element of the list.

"Count" method

Output the size of the enumeration or the number of elements of a list.

```
CFRESULT Count(uint32_t *pCount)
```

pCount
[out]: Points to the value for the number of elements of the list.

See also

IConnectionResult (Page 8094)

IConnectionSet (Page 8104)

IConnectionStatusResult

Description

The C++ interface "IConnectionStatusResult" provides methods for access to the status of connections.

Members

The following methods are specified in the interface:

"GetName" method

Return name of the connection.

```
CFRESULT GetName(CFSTR *pName)
```

`pName`
[out]: Points to the name of the connection.

"GetConnectionStatus" method

Return status of the connection.

```
CFRESULT GetConnectionStatus(CFENUM *pConnectionStatus)
```

`pConnectionStatus`
[out]: Points to the enumeration, which can contain the following values:

- `Disabled` (0)
- `Connecting` (1)
- `Connected` (2)
- `Disconnecting` (3)
- `Disconnected` (4)
- `Reconnecting` (5)

"GetError" method

Return error code of the connection.

```
CFRESULT GetError(uint32_t *pError)
```

`pError`
[out]: Points to the error code.

Example

Output status of a certain connection:

Copy code

```
void ConnectionSet_GetConnectionState(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"ConnectionSet"), &pUnk);

   IConnectionSetPtr pConnectionsetPtr(pUnk);
   CCfSmartString strName(L"HMI-Connection");
   CCfString strName1(L"HMI-ConnectionS7Plus");
   CCfArrayVariant vtArrayVaiarnt;
   vtArrayVaiarnt.Append(strName);
   vtArrayVaiarnt.Append(strName1);
   ICfArrayVariantPtr connectionNames;
   vtArrayVaiarnt.DetachEnumerator(&connectionNames);
   pConnectionsetPtr->Add(connectionNames);

   IConnectionStatusResultEnumeratorPtr pConnectionStatusResultEnum;
   IConnectionStatusResultPtr pConnectionStatusresult;
   pConnectionsetPtr->GetConnectionState(&pConnectionStatusResultEnum);

   uint32_t nCount;
   pConnectionStatusResultEnum->Count(&nCount);
   for (int32_t i = 0; i < (int32_t)nCount; i++)
   {
      pConnectionStatusResultEnum->MoveNext();
      pConnectionStatusResultEnum->Current(&pConnectionStatusresult);

      CCfString strName;
      pConnectionStatusresult->GetName(&strName);
      std::cout << "ConnectionName:" << strName.ToUTF8() << std::endl;
      CFENUM enConnectionState;
      pConnectionStatusresult->GetConnectionStatus(&enConnectionState);
      HmiConnectionState enumconnectionState =
static_cast<HmiConnectionState>(enConnectionState);
      ConnectionState(enumconnectionState);
   }
}
```

IConnection (Page 8101)

IConnectionStatusResultEnumerator (Page 8100)

IConnectionStatusResultEnumerator

Description

The "IConnectionStatusResultEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of connection status of the Runtime system. The enumeration is used, for example, when reading out connections of a connection set.

All the methods return CF_SUCCESS following successful execution.

Members

The following methods are specified in the interface:

"Current" method

Output the current element of the enumeration of a list.

```
CFRESULT Current(IConnectionStatusResult **ppItem)
```

`ppItem`
[out]: Points to the current "IConnectionStatusResult" object as an element of the list.

"MoveNext" method

Go to the next element of the enumeration of a list.

```
CFRESULT MoveNext()
```

"Reset" method

Reset the current position in the enumeration of a list.

```
CFRESULT Reset()
```

The "MoveNext" method moves afterwards to the first element of the list.

"Count" method

Output the size of the enumeration or the number of elements of a list.

```
CFRESULT Count(uint32_t *pCount)
```

`pCount`
[out]: Points to the value for the number of elements of the list.

See also

IConnectionStatusResult (Page 8097)

IConnectionSet (Page 8104)

IConnection

Description

The C++ interface "IConnection" provides properties and methods for access to a connection.

Members

The following methods are specified in the interface:

"GetName" method

Return name of the connection.

```
CFRESULT GetName(CFSTR *pName)
```

`pName`
[out]: Points to the name of the connection.

"SetName" method

Change name of the connection.

```
CFRESULT SetName(CFSTR name)
```

`name`
[in]: Name of the connection

"Read" method

Read connection details synchronously from the Runtime system.

```
CFRESULT Read(IConnectionResult **ppConnectionResult)
```

`ppConnectionResult`
[out]: Points to an object of type "IConnectionResult" that contains the connection details.

"GetConnectionState" method

Return connection status of a connection.

```
CFRESULT GetConnectionState(IConnectionStatusResult
**ppConnectionStatusResult)
```

`ppConnectionStatusResult`
[out]: Points to an object of type "IConnectionStatusResult" that contains the status of connections.

"SetConnectionMode" method

Change connection status of a connection.

```
CFRESULT SetConnectionMode(CFENUM connectionmode)
```

`connectionmode`
[in]: Enumeration which contains the mode of connections:

- `Disabled` (0)
- `Enabled` (1)

Examples

Change status of a connection:

Copy code

```
void Connection_SetConnectionState(IRuntimePtr pRuntime, ConnectionMode connectionMode)
{
	ICfUnknownPtr pUnk;
	pRuntime->GetObject(CCfString(L"Connection"), &pUnk);

	IConnectionPtr pConnection(pUnk);
	CCfSmartString daName = L"HMI-Connection";
	pConnection->SetName(daName.AllocCFSTR());
	pConnection->SetConnectionMode(int32_t(connectionMode));
}
```

IConnectionResult (Page 8094)

IConnectionStatusResult (Page 8097)

IConnectionSet (Page 8104)

IConnectionReadNotification

Description

The C++ interface "IConnectionReadNotification" defines a callback method for implementation of operations following read operations of connections.

Members

The following method is specified in the interface:

"OnReadComplete" method

Callback method is called following read operations of connections.

The "OnReadComplete" callback method is called when the `IConnectionSet.ReadAsync` method is used.

```
CFRESULT OnReadComplete(IConnectionResultEnumerator *pEnumerator,
uint32_t errorCode, int32_t contextId)
```

- `pEnumerator`
  [out]: Points to an "IConnectionResultEnumerator" object that contains the enumeration of the connection details.
- `errorCode`
  [out]: Error code for the asynchronous operation.
- `contextId`
  [out]: ContextID as additional identification feature of the connections.

Example

Read out connection asynchronously:

Copy code

```
void ConnectionSet_ReadAsync(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"ConnectionSet"), &pUnk);
   IConnectionSetPtr pConnectionset(pUnk);
   IConnectionResultPtr pConnectionResult;
   CCfString strName(L"HMI-Connection");
   CCfString strName1(L"HMI-ConnectionS7Plus");
   CCfArrayVariant vtArrayVaiarnt;
   vtArrayVaiarnt.Append(strName);
   vtArrayVaiarnt.Append(strName1);
   ICfArrayVariantPtr connectionNames;
   vtArrayVaiarnt.DetachEnumerator(&connectionNames);
   pConnectionset->Add(connectionNames);
  CCfRefPtr<CConnectionReadNotification>pRead = new CConnectionReadNotification(pRuntime);
   IConnectionReadNotification *pNotification = pRead;
   pConnectionset->ReadAsync(pNotification);
}
```

See also

IConnectionSet (Page 8104)

IConnectionStateChangeNotification

Description

The C++ interface "IConnectionStateChangeNotification" defines a callback method for implementing asynchronous change monitoring of connections.

Members

The following method is specified in the interface:

"OnDataChanged" method

Callback method is called after changes of a monitored connection.

The "OnDataChanged" callback method is called when the `IConnectionSet.Subscribe` method is used.

```
CFRESULT OnDataChanged(IConnectionStatusResultEnumerator*
pEnumerator, uint32_t errorCode, int32_t contextId)
```

- `pEnumerator`
  [out]: Points to an "IConnectionStatusResultEnumerator" object that contains the enumeration of the connection status.
- `errorCode`
  [out]: Error code for the asynchronous operation.
- `contextId`
  [out]: ContextID as additional identification feature of the connections.

Example

Monitor connection status:

Copy code

```
void ConnnectionSet_Subscribe(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"ConnectionSet"), &pUnk);
   IConnectionSetPtr pConnectionsetPtr(pUnk);
   CCfString strName(L"RUNTIME_1::Connection3");
   CCfString strName1(L"HMI-ConnectionS7Plus");
   CCfArrayVariant vtArrayVaiarnt;
   vtArrayVaiarnt.Append(strName);
   vtArrayVaiarnt.Append(strName1);
   ICfArrayVariantPtr connectionNames;
   vtArrayVaiarnt.DetachEnumerator(&connectionNames);
   pConnectionsetPtr->Add(connectionNames);
   CConnectionSubscriptionNotification *pSubscribe = new
CConnectionSubscriptionNotification();
   IConnectionStateChangeNotification *pNotification = pSubscribe;
   pConnectionsetPtr->Subscribe(pNotification);
}
```

See also

IConnectionSet (Page 8104)

IConnectionSet

Description

The C++ interface "IConnectionSet" specifies properties and methods for optimized access to several connections of the Runtime system.

After initialization of the "IConnectionSet" object, you have read/write access to multiple connections in one call. Simultaneous access takes place with better performance and lower communication load than single access to multiple connections.

Members

The following methods are specified in the interface:

"SetContextId" method

Change ID as additional identification feature of a connection. The ContextId can, for example, be used to recognize identically named connections.

```
CFRESULT SetContextId(uint32_t id)
```

`id`
[in]: ContextID of the connection

"GetContextId" method

Return ID as additional identification feature of a connection. The ContextId can, for example, be used to recognize identically named connections.

```
CFRESULT GetContextId(uint32_t *pId)
```

`pId`
[out]: Points to the ContextID of the connection.

"Add" method

Add connections to a connection set.

```
CFRESULT Add(ICfArrayVariant *connectionNames)
```

`connectionNames`
[in]: Points to an array that contains the names of connections.

"Remove" method

Remove individual connection from connection set.

```
CFRESULT Remove(CFSTR connectionName)
```

`connectionName`
[in]: Name of the connection.

"Clear" method

Remove all connections from connection set.

```
CFRESULT Clear()
```

"GetCount" method

Return number of connections of a connection set list.

```
CFRESULT GetCount(int32_t *pCount)
```

`pCount`
[out]: Points to the number of connections in the connection set.

"Read" method

Read connection details of all connections of the connection set synchronously from the Runtime system.

```
CFRESULT Read(IConnectionResultEnumerator
**ppConnectionResultEnumerator)
```

`ppConnectionResultEnumerator`
[out]: Points to the enumeration of the details of the individual connections.

"ReadAsync" method

Read connection details of all connections of the connection set asynchronously from the Runtime system.

```
CFRESULT ReadAsync(IConnectionReadNotification *pReadReply)
```

`pReadReply`
[in]: Points to the "IConnectionReadNotification" callback interface for read operations and returns the "IConnectionResultEnumerator" object.

"GetConnectionState" method

Read connection status synchronously from the Runtime system.

```
CFRESULT GetConnectionState(IConnectionStatusResultEnumerator
**ppConnectionStatusResultEnumerator)
```

`ppConnectionStatusResultEnumerator`
[out]: Points to an object of type "IConnectionStatusResultEnumerator" that contains the enumeration of the connection status.

"Subscribe" method

Subscribe all connections of a connection set asynchronously for change monitoring.

```
CFRESULT Subscribe(IConnectionStateChangeNotification
*ppNotificationCB)
```

`ppNotificationCB`
[in]: Points to the "IConnectionStateChangeNotification" callback interface for monitoring and returns the "IConnectionStatusResultEnumerator" object following a change.

"CancelSubscribe" method

Cancel change monitoring of all connections of a connection set.

```
CFRESULT CancelSubscribe()
```

Examples

Monitor connection:

Copy code

```
void ConnnectionSet_Subscribe(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"ConnectionSet"), &pUnk);
   IConnectionSetPtr pConnectionsetPtr(pUnk);
   CCfString strName(L"RUNTIME_1::Connection3");
   CCfString strName1(L"HMI-ConnectionS7Plus");
   CCfArrayVariant vtArrayVaiarnt;
   vtArrayVaiarnt.Append(strName);
   vtArrayVaiarnt.Append(strName1);
   ICfArrayVariantPtr connectionNames;
   vtArrayVaiarnt.DetachEnumerator(&connectionNames);
   pConnectionsetPtr->Add(connectionNames);
   CConnectionSubscriptionNotification *pSubscribe = new
CConnectionSubscriptionNotification();
   IConnectionStateChangeNotification *pNotification = pSubscribe;
   pConnectionsetPtr->Subscribe(pNotification);
}
```

Read out connection asynchronously:

Copy code

```
void ConnectionSet_ReadAsync(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"ConnectionSet"), &pUnk);
   IConnectionSetPtr pConnectionset(pUnk);
   IConnectionResultPtr pConnectionResult;
   CCfString strName(L"HMI-Connection");
   CCfString strName1(L"HMI-ConnectionS7Plus");
   CCfArrayVariant vtArrayVaiarnt;
   vtArrayVaiarnt.Append(strName);
   vtArrayVaiarnt.Append(strName1);
   ICfArrayVariantPtr connectionNames;
   vtArrayVaiarnt.DetachEnumerator(&connectionNames);
   pConnectionset->Add(connectionNames);
  CCfRefPtr<CConnectionReadNotification>pRead = new CConnectionReadNotification(pRuntime);
   IConnectionReadNotification *pNotification = pRead;
   pConnectionset->ReadAsync(pNotification);
}
```

Add/remove connection for connection set

Copy code

```
void Connection_AddRemove(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"ConnectionSet"), &pUnk);
   IConnectionSetPtr pConnectionsetPtr(pUnk);
   CCfString strName(L"HMI-Connection");
   CCfSmartString strName1(L"HMI-ConnectionS7Plus");
   CCfArrayVariant vtArrayVaiarnt;
   vtArrayVaiarnt.Append(strName);
   vtArrayVaiarnt.Append(strName1);
   ICfArrayVariantPtr connectionNames;
   vtArrayVaiarnt.DetachEnumerator(&connectionNames);
   pConnectionsetPtr->Add(connectionNames);
   int32_t count;
   pConnectionsetPtr->GetCount(&count);

   pConnectionsetPtr->Remove(strName1.AllocCFSTR());
   pConnectionsetPtr->GetCount(&count);

   pConnectionsetPtr->Clear();
   pConnectionsetPtr->GetCount(&count);
}
```

20.3.9.6 Interfaces of the Plant Model

IPlantModel

Description

The C++ interface "IPlantModel" specifies methods for access to object instances of the plant model of a Runtime system. The "IPlantModel" object represents the plant model of the graphical Runtime system.

The interface inherits from the "ICfDispatch" interface.

Formatting of a hierarchy path

A hierarchy path of object instances consists of several components and has the following syntax:

```
[SystemName].HierarchyName::[PlantObjectID/.../]PlantObjectID
```

The system name can be omitted for referencing a local hierarchy. The dot before the hierarchy name must stay.

Members

The following methods are specified in the interface:

"GetPlantObject" method

Supplies an "IPlantObject" instance.

```
CFRESULT GetPlantObject(const CFSTR Node, IPlantObject**
ppPlantObject)
```

- `Node`
  [in]: Identifies an `IPlantObject` instance by its name or its path in the hierarchy.
- `ppPlantObject`
  [out]: Points to an "IPlantObject" instance.

"GetPlantObjectsByType" method

Supplies an enumeration with "IPlantObject" instances that have a specific type.

```
GetPlantObjectsByType(const CFSTR plantObjectTypeFilter, const
CFSTR ViewFilter, IPlantObjectEnumerator** ppPlantObjects)
```

- `plantObjectTypeFilter`
  [in]: Filter for the "IPlantObject" type on which the instances are based.
- `ViewFilter`
  [in]: Filter for the path in the hierarchy. Only instances from a specific node are returned.
- `ppPlantObjects`
  [out]: Points to an "IPlantObjectEnumerator" enumeration with "IPlantObject" instances.

"GetObjectsByPropertyName" method

Supplies an enumeration with "IPlantObject" instances that have specific properties and originate in a specific plant node.

```
GetPlantObjectsByPropertyNames(const CFVARIANT PropertyNames, const
CFSTR ViewFilter, IPlantObjectEnumerator** ppPlantObjects)
```

- `PropertyNames`
  [in]: Property names
- `ViewFilter`
  [in]: Filter for a hierarchy path.
- `ppPlantObjects`
  [out]: Points to an "IPlantObjectEnumerator" enumeration with "IPlantObject" instances.

"GetPlantObjectsByExpression" method

Supplies an enumeration with "IPlantObject" instances. The instances are filtered by type and property values.

```
GetPlantObjectsByExpression(const CFVARIANT PropertyNames, const
CFSTR plantObjectTypeFilter, const CFSTR expressionFilter, const
CFSTR ViewFilter, IPlantObjectEnumerator** ppPlantObjects)
```

- `PropertyNames`
  [in]: Property names
  If the list contains multiple values, all properties must be available at the object.
- `plantObjectTypeFilter`
  [in]: Filter for the object type on which the instances are based.
- `expressionFilter`
  [in]: An expression that is a filter for the property values.
- `ViewFilter`
  Filter for a hierarchy path.
- `ppCpmNodes`
  [out]: Points to an "IPlantObjectEnumerator" enumeration with "IPlantObject" instances.

Example

Hierarchy path	Referenced object instance
`System2.TechnologicalHierarchy::P1/S1/L2/LeftPump`	References the "LeftPump" object instance in the "TechnologicalHierarchiy" of system2.
`.TechnologicalHierarchy::P1/S1/L2/LeftPump`	References the "LeftPump" object instance in the "TechnologicalHierarchiy" of the local system.
`U4711`	References the "U4711" object instance of the local system.
`System2::U4711`	References the "U4711" object instance of System2.

Copy code

```
void PlantModelGetPlantObjectsByType(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"PlantModel"), &pUnk);
   IPlantModelPtr pPlantModel(pUnk);
   IPlantObjectEnumeratorPtr pPlantObjectEnum;
   pPlantModel->GetPlantObjectsByType(CCfString(L"BLOWER").Get(), CCfString(L"").Get(),
&pPlantObjectEnum);
   IPlantObjectPtr pItem;
   pPlantObjectEnum->MoveNext();
   while (CF_SUCCEEDED(pPlantObjectEnum->Current(&pItem)))
   {
      DisplayNodeInfo(pItem);
      pPlantObjectEnum->MoveNext();
   }

void PlantModelGetPlantObjectsByExpression(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"PlantModel"), &pUnk);
   IPlantModelPtr pPlantModel(pUnk);
   IPlantObjectEnumeratorPtr pPlantObjectEnum;
   CCfString str1 = L"NumberOfNodes";
   CCfString str2 = L"Quality";
   CCfSafeArray daSafeArray(CF_VT_STR, 1U, 2U);
   int32_t index = 0;
   daSafeArray.PutElement(&index, (void*)&str1);
   ++index;
   daSafeArray.PutElement(&index, (void*)&str2);
   ++index;
   CCfVariant vtProperties;
   daSafeArray.Detach(&vtProperties);
   pPlantModel->GetPlantObjectsByExpression(vtProperties, CCfString(L"BLOWER").Get(),
CCfString(L"NumberOfNodes>=0"), CCfString(L"RUNTIME_1.hierarchy").Get(),
&pPlantObjectEnum);

   pPlantObjectEnum->MoveNext();
   IPlantObject* pPlantObject;
   while (CF_SUCCEEDED(pPlantObjectEnum->Current(&pPlantObject)))
   {
      DisplayNodeInfo(pPlantObject);
      pPlantObjectEnum->MoveNext();
   }
}
```

IPlantObject

Description

The C++ interface "IPlantObject" specifies methods for handling object instances of the plant model of a Runtime system.

An object instance in the plant model is based on an object type and its data structure. Each object instance receives its position within the plant hierarchy by assigning it to a hierarchy node.

The interface inherits from the "ICfDispatch" interface.

Formatting of a hierarchy path

A hierarchy path of object instances consists of several components and has the following syntax:

```
[SystemName].HierarchyName::[NodeID/.../]NodeID
```

The system name can be omitted for referencing a local hierarchy. The dot before the hierarchy name must stay.

Members

The following methods are specified in the interface:

"GetName" method

Supplies the name of the "IPlantObject" instance for unique identification.

```
CFRESULT GetName(CFSTR* pName)
```

- `pName`
  [out]: Name of the instance

"GetParent" method

Supplies the parent of the "IPlantObject" instance in the hierarchy.

```
CFRESULT GetParent(IPlantObject** ppParent)
```

- `ppParent`
  [out]: The parent as "IPlantObject" instance.

"GetChildren" method

Supplies an enumeration with the children of the "IPlantObject" instance in the hierarchy.

```
CFRESULT GetChildren(IPlantObjectEnumerator** ppChildren)
```

- `ppChildren`
  [out]: An enumeration of the type "IPlantObjectEnumerator" with child object instances.

"GetPlantViewPaths" method

Supplies a map with hierarchy names and hierarchy paths that the "IPlantObject" instance has in all hierarchies in which it is included.

```
CFRESULT GetPlantViewPaths(ICfMapStringToVariant **pViewPaths)
```

- `pViewPaths`
  [out]: A map with String/String pairs (hierarchy name to hierarchy path).

"GetCurrentPlantView" method

Supplies the path and names of the "IPlantObject" instance in the current hierarchy.

If the "IPlantObject" instance is only contained in one hierarchy, this path is returned.

```
CFRESULT GetCurrentPlantView)(CFSTR* pView)
```

- `pView`
  [out]: Hierarchy path and name of the "IPlantObject" instance.

"SetCurrentPlantView" method

"CurrentPlantView" is the basis for navigation with the "GetParent" or "GetChildren" methods. If the "IPlantObject" instance is contained in several hierarchies, the path must be set via "SetCurrentPlantView" before the "GetParent" or "GetChildren" method can be used.

```
CFRESULT SetCurrentPlantView)(CFSTR const& View)
```

- `View`
  [in]: The current hierarchy

"GetProperty" method

Supplies a property of the "IPlantObject" instance.

```
CFRESULT GetProperty(const CFSTR propertyName,
IPlantObjectProperty** ppPlantObjectProperty)
```

- `propertyName`
  [in]: Name of a property of the "IPlantObject" instance
- `ppPlantObjectProperty`
  [out]: Points to an "IPlantObjectProperty" instance.

"GetProperties" method

Supplies a two-dimensional list (name-object pairs) of the data structure of the "IPlantObject" instance. The list allows access to the instance properties.

```
CFRESULT GetProperties(const CFVARIANT propertyNames,
IPlantObjectPropertySet** ppPlantObjectPropertySet)
```

- Optional: `propertyNames`
  [in]: List with names of one or multiple properties of the "IPlantObject" instance.
  Without "propertyNames" parameter, all properties of the instance are referenced in the list.
- `ppPlantObjectPropertySet`
  [out]: Points to the list of the type "IPlantObjectPropertySet" that contains the names of one or multiple properties of the "IPlantObject" instance.

"GetActiveAlarms" method

Supplies all active alarms that the "IPlantObject" instance contains at the time it is called in the active hierarchy. Unlike with an AlarmSubscription, no status changes or new alarms are signaled that occur after the function call. Users can filter the alarms or specify a SystemName if they only want to receive the active alarms of a specific system.

```
CFRESULT GetActiveAlarms(uint32_t language, CFBOOL IncludeChildren,
CFSTR filter,IN IPlantObjectAlarmCallback* pCallback)
```

- `language`
  [in]: Language code of the language for all texts of an alarm and the filters. Refer to the section Locale IDs of the supported languages (Page 7829).
- `IncludeChildren`
  [in]: The active alarms of the child instances are returned as well.
- `filter`
  [in]: SQL-type string for filtering the alarm texts. The filter can contain operators. See also Syntax of the alarm filter (Page 7828).
- `pCallback`
  [in]: Callback pointer.

"CreateAlarmSubscription" method

Supplies a "PlantObjectAlarmSubscription" that can be used to start and stop an alarm subscription.

```
CFRESULT CreateAlarmSubscription)(IPlantObjectAlarmSubscription**
ppPlantObjectAlarmSubscription)
```

- `ppPlantObjectAlarmSubscription`
  [out] Points to a "PlantObjectAlarmSubscription" instance.

Example

Copy code

```
void PlantObjectGetProperties(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"PlantModel"), &pUnk);
   IPlantModelPtr pPlantModel(pUnk);
   IPlantObjectPtr pPlantObject;
   CCfString strNode = L".hierarchy::PlantView/Unit1";
   //gets node for specified Node path
   pPlantModel->GetPlantObject(strNode.Get(), &pPlantObject);

   //empty property - so all node members should be read
   CCfVariant vtProperties;
   IPlantObjectPropertySetPtr pPlantObjectPropertySet;
   // get the PlantObject properties by property names
   pPlantObject->GetProperties(vtProperties, &pPlantObjectPropertySet);

   uint32_t nCount = 0;
   pPlantObjectPropertySet->GetCount(&nCount);
   std::cout << "Count :" << nCount << std::endl;
}
```

IPlantObjectProperty

Description

The C++ interface "IPlantObjectProperty" specifies the handling of properties of object instances of the plant model of a Runtime system. The properties represent the data structure of an object instance.

The object instance communicates with the automation system through the properties of the data structure. The values of the properties are obtained from linked process tags or internal tags.

You reference an object using the `IPlantObject.GetProperty` or `IPlantObject.GetProperties` methods.

The interface inherits from the "ICfDispatch" interface.

Members

The following methods are specified in the interface:

"GetName" method

Supplies the name of the property.

```
CFRESULT GetName(CFSTR *pName)
```

- `pName`
  [out]: Points to the name of the property.

"Read" method

Reads the value of the "IPlantObjectProperty" instance synchronously and returns it as an "IPlantObjectPropertyValue" object. The value, the quality code and the time stamp of the property are determined when the property is read.

```
CFRESULT Read(IPlantObjectPropertyValue**
ppPlantObjectPropertyValue)
```

- `ppPlantObjectPropertyValue`
  [out]: Values of the property as "IPlantObjectPropertyValue" instance

"Write" method

Writes the value synchronously to the "IPlantObjectProperty" instance.

```
CFRESULT Write)(const CFVARIANT value)
```

- `value`
  [in]: New process value of the property

Example

Copy code

```
void PlantObjectReadproperty(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"PlantModel"), &pUnk);
   IPlantModelPtr pPlantModel(pUnk);
   IPlantObjectPtr pPlantObject;
   CCfString strNode = L".hierarchy::PlantView/Unit1";
   //gets node for specified Node path
   pPlantModel->GetPlantObject(strNode.Get(), &pPlantObject);
   //empty property - so all node members should be read
   CCfVariant vtProperties;
   CCfSafeArray daPropertyNames(CF_VT_STR, 1U, 1U);
   int32_t index = 0;
   CCfString strName(L"DateActivation");
   daPropertyNames.PutElement(&index, &strName);
   daPropertyNames.Detach(&vtProperties);
   IPlantObjectPropertySetPtr pPlantObjectPropertySet;
   // get the PlantObject properties by property names
   pPlantObject->GetProperties(vtProperties, &pPlantObjectPropertySet);
   CCfString strName(L"NumberOfNodes");
   IPlantObjectPropertyPtr PlantObjectProperty;
   //get the PlantObject property by name
   pPlantObject->GetProperty(strName.Get(), &PlantObjectProperty);
   IPlantObjectPropertyValuePtr pPlantObjectPropertyValue;
   // Read PlantObject Property
   PlantObjectProperty->Read(&pPlantObjectPropertyValue);

   CCfString strName;
   pPlantObjectPropertyValue->GetPlantObjectPropertyName(&strName);
   std::cout << "PlantModelPropertyName:" << strName.ToUTF8() << std::endl;
   int64_t qc;
   pPlantObjectPropertyValue->GetQuality(&qc);
   std::cout << "Quality:" << qc << std::endl;
   int64_t ec;
   pPlantObjectPropertyValue->GetError(&ec);
   std::cout << "Error:" << ec << std::endl;
   CCfDateTime64 dt;
   pPlantObjectPropertyValue->GetTimeStamp(&dt);
   std::cout << "DateTime:" << dt.GetDateTimeString().ToUTF8() << std::endl;
   CCfVariant vtVal;
   pPlantObjectPropertyValue->GetValue(&vtVal);
   std::cout << "Value:" << vtVal.uint64 << std::endl;
}
```

IPlantObjectPropertyValue

Description

The C++ interface "IPlantObjectPropertyValue" specifies the handling of process tag properties of the Runtime system.

Members

The following methods are specified in the interface:

"GetPlantObjectPropertyName" method

Supplies the name of the tag.

```
CFRESULT GetPlantObjectPropertyName(CFSTR* pName)
```

- `pName`
  [out]: Points to the name.

"GetValue" method

Supplies the tag value.

```
CFRESULT GetValue(CFVARIANT* pValue)
```

- `pValue`
  [out]: Points to the process value.

"GetQuality" method

Supplies the quality code of the tag.

```
CFRESULT GetQuality(int64_t* pQualityCode)
```

- `pQualityCode`
  [out]: Points to the quality code.

"GetTimeStamp" method

Supplies the time stamp of the last modification to the tag.

```
CFRESULT GetTimeStamp(CFDATETIME64* pTimeStamp)
```

- `pTimeStamp`
  [out]: Points to the time stamp.

"GetError" method

Supplies the error code of the tag.

```
CFRESULT GetError(int64_t* pErrorCode)
```

- `pErrorCode`
  [out]: Points to the error code.

Example

For example, see IPlantObjectProperty (Page 8115).

IPlantModelPropertySubscriptionNotification

Description

The C++ interface "IPlantModelPropertySubscriptionNotification" defines methods for implementing asynchronous change monitoring of object instance properties. The methods are used by the C++ interface "ICpmNodePropertySet".

All the methods return CF_SUCCESS following successful execution.

The interface inherits the "ICfUnknown" interface.

Members

The following methods are specified in the interface:

"OnDataChanged" method

Callback method is called when a monitored object instance property is changed.

```
CFRESULT OnDataChanged(IPlantObjectPropertyValueEnumerator*
pEnumerator)
```

- `pEnumerator`:
  [in]: Points to the "IPlantObjectPropertyValueEnumerator" object that provides access to an enumeration of "IPlantObjectPropertyValue" instances.

Example

Register a PropertySet for monitoring:

Copy code

```
void PlantObjectSubscribePropertySet(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"PlantModel"), &pUnk);

   IPlantModelPtr pPlantModel(pUnk);
   IPlantObjectPtr pPlantObject;
   CCfString strNode = L".hierarchy::PlantView/Unit1/Filler1";
   //gets node for specified Node path
   pPlantModel->GetPlantObject(strNode.Get(), &pPlantObject);

   //empty property - so all node members should be read
   CCfVariant vtProperties;
   IPlantObjectPropertySetPtr pPlantObjectPropertySet;
   // get the PlantObject properties by property names
   pPlantObject->GetProperties(vtProperties, &pPlantObjectPropertySet);

   CPlantModelPropertySubscriptionNotification* pSubscribe = new
CPlantModelPropertySubscriptionNotification();
   IPlantModelPropertySubscriptionNotification* pNotification = pSubscribe;
   //Susbcribe for all PlantObject properties
   pPlantObjectPropertySet->Subscribe(pNotification);
}

CFRESULT CFCALLTYPE
CPlantModelPropertySubscriptionNotification::OnDataChanged(IPlantObjectPropertyValueEnumer
ator* pEnumerator)
{
   uint32_t nCount = 0;
   pEnumerator->Count(&nCount);
   for (int i = 0;i < (int32_t)nCount; i++)
   {
      pEnumerator->MoveNext();
      IPlantObjectPropertyValue* pPlantModelPropertyValue;
      if (CF_SUCCEEDED(pEnumerator->Current(&pPlantModelPropertyValue)) && nullptr !=
pPlantModelPropertyValue)
      {
         CCfString strName;
         pPlantModelPropertyValue->GetPlantObjectPropertyName(&strName);
         std::cout << "Name:" << strName.ToUTF8() << std::endl;
         int64_t qc;
         pPlantModelPropertyValue->GetQuality(&qc);
         std::cout << "Quality:" << qc << std::endl;
         int64_t ec;
         pPlantModelPropertyValue->GetError(&ec);
         std::cout << "Error:" << ec << std::endl;
         CCfDateTime64 dt;
         pPlantModelPropertyValue->GetTimeStamp(&dt);
         std::cout << "DateTime:" << dt.GetDateTimeString().ToUTF8() << std::endl;
         CCfVariant vtVal;
         pPlantModelPropertyValue->GetValue(&vtVal);
         std::cout << "Value:" << vtVal.uint64 << std::endl;
```

Copy code

```
        }
    }
    this->SetEvent();
    return CF_SUCCESS;
}
```

IPlantObjectPropertyValueEnumerator

Description

The C++ interface "IPlantObjectPropertyValueEnumerator" specifies methods for handling the enumeration of "IPlantObjectPropertyValue" instances.

All the methods return `CF_SUCCESS` following successful execution.

The interface inherits the "ICfUnknown" interface.

Members

The following methods are specified in the interface:

"Current" method

Supplies the current element of the enumeration.

```
Current(IPlantObjectPropertyValue** ppItem)
```

- `ppItem`
  [out]:

"MoveNext" method

Move to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Reset" method

Resets the current position in the enumeration to the first element.

```
CFRESULT Reset()
```

"MoveNext" then supplies the first element of the enumeration.

"Count" method

Output the size of the enumeration or the number of elements in an enumeration.

```
CFRESULT Count(uint32_t *pValue)
```

- `value`
  [out]: Points to the value for the number of elements in the enumeration.

Example

For example, see IPlantModelPropertySubscriptionNotification (Page 8118).

IPlantObjectPropertySet

Description

The C++ interface "IPlantObjectPropertySet" specifies methods for optimized access to several "IPlantObjectProperty" instances of an "IPlantObject" instance of the Runtime system.

After initialization of the "IPlantObjectPropertySet" object, you have read/write access to multiple "IPlantObjectProperty" instances in one call. Simultaneous access has better performance and a lower communication load than single access to multiple properties.

The interface inherits from the "ICfDispatch" interface.

Members

The following methods are specified in the interface:

"GetContextID" method

Supplies an ID as additional identification feature of a property. "ContextId" can, for example, be used to recognize properties having the same name but from different systems.

Default value -1: "ContextId" is not used.

```
CFRESULT GetContextId)(int32_t* pContextId)
```

- `pContextId`
  [out]: "ContextId" of the property

"SetContextID" method

Sets an ID as additional identification feature of a property. "ContextId" can, for example, be used to recognize properties having the same name but from different systems.

Default value -1: "ContextId" is not used.

```
CFRESULT SetContextId(int32_t contextId)
```

- `contextId`
  [in]: "ContextId" of the property

"Read" method

Supplies all values of the "IPlantObjectProperty" instances contained in the "IPlantObjectPropertySet" instance. The values are read synchronously.

```
CFRESULT Read(IPlantObjectPropertyValueEnumerator**
ppPlantObjectPropertyValueEnumerator)
```

- `ppPlantObjectPropertyValueEnumerator`
  [out]: Points to the enumeration of the tag values as an "IPlantObjectPropertyValueEnumerator" object.

"ReadAsync" method

Reads the values of all "IPlantObjectProperty" instances of the "IPlantObjectPropertySet" instance asynchronously.

```
CFRESULT ReadAsync(IPlantObjectPropertySetReadReply* pReadReply)
```

- `pReadReply`
  [in]: Points to the "IPlantObjectPropertySetReadReply" object that implements the callback interface for read operations.

"Write" method

Writes the values of the "IPlantProperty" instances of the "PlantObjectPropertySet" instance synchronously to the Runtime system.

```
CFRESULT Write(HmiUnified::Rt::IErrorResultEnumerator**
ppEnumerator)
```

- `pWriteReply`
  [out]: Points to an "IErrorResultEnumerator" object that contains the enumeration with errors for the write operations of the "IPlantObjectProperty" instances.

"WriteAsync" method

Writes the values of all "IPlantObjectProperty" instances of the "PlantObjectPropertySet" instance asynchronously to the Runtime system.

```
CFRESULT WriteAsync(IPlantObjectPropertySetWriteReply *pWriteReply)
```

- `pWriteReply`
  [in]: Points to the "IPlantObjectPropertySetWriteReply" object that implements the callback interface for write operations.

"GetCount" method

Supplies the number of properties of the "IPlantObjectPropertySet" instance.

```
CFRESULT GetCount(uint32_t *pCount)
```

- `pCount`
  [out]: Points to the number of properties.

"Subscribe" method

Subscribes all properties of the "IPlantObjectPropertySet" instance asynchronously for change monitoring.

```
CFRESULT Subscribe(IPlantModelPropertySubscriptionNotification*
pPlantModelSubscriptionCallback)
```

- `pPlantModelSubscriptionCallback`
  [in]: Points to the "IPlantObjectPropertySubscriptionNotification" object that implements the callback interface of the change monitoring.

"CancelSubscribe" method

Cancels change monitoring for all properties of the "IPlantObjectPropertySet" instance.

```
CFRESULT CancelSubscribe()
```

"Add" method

Adds an "IPlantObjectProperty" instance with property value or more "IPlantObjectProperty" instances to the "IPlantObjectPropertySet" instance.

```
CFRESULT Add(ICfArrayVariantPtr propertyNames)
```

- `propertyNames`
  [in]: Array with names of several "IPlantObjectProperty" instances

or

```
CFRESULT Add(const CFSTR propertyName, const CFVARIANT value)
```

- `propertyName`
  [in]: Name of the "IPlantObjectProperty" instance
- `value`
  [in]: New process value of the "IPlantObjectProperty" instance

"Remove" method

Removes a property from the "IPlantObjectPropertySet" instance.

```
CFRESULT Remove(const CFSTR propertyName)
```

- `propertyName`
  [in]: Name of the property that is being removed.

"Clear" method

Removes all properties from the "IPlantObjectPropertySet" instance.

```
CFRESULT Clear()
```

New example

Copy code

```
void PlantObjectWriteAsyncPropertySet(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"PlantModel"), &pUnk);
   IPlantModelPtr pPlantModel(pUnk);
   IPlantObjectPtr pPlantObject;
   CCfString strNode = L".hierarchy::PlantView/Unit1";
   //gets node for specified Node path
   pPlantModel->GetPlantObject(strNode.Get(), &pPlantObject);

   //empty property - so all node members should be read
   CCfVariant vtProperties;
   IPlantObjectPropertySetPtr pPlantObjectPropertySet;
   // get the PlantObject properties by property names
   pPlantObject->GetProperties(vtProperties, &pPlantObjectPropertySet);

   CCfString strName(L"NumberOfNodes");
   CCfVariant vtValue(1000);
   pPlantObjectPropertySet->Add(strName, vtValue);

   CPlantObjectPropertySetWriteReply* pReply = new CPlantObjectPropertySetWriteReply();
   IPlantObjectPropertySetWriteReplyPtr pWritReply = pReply;
   //Write PlantObject properties values asynchronously
   pPlantObjectPropertySet->WriteAsync(pWritReply);
}
```

IPlantObjectPropertySetReadReply

Description

The C++ interface "IPlantObjectPropertySetReadReply" defines the "OnReadComplete" method as callback method of a "ReadAsync" call. The method is used by the C++ interface "IPlantObjectPropertySet".

Members

The following methods are specified in the interface:

"OnReadComplete" method

The "OnReadComplete" callback method is called when the "ReadAsync" method is used.

```
CFRESULT OnReadComplete(CFVARIANT
systemError, IPlantObjectPropertyValueEnumerator*
pPlantObjectPropertyValueEnumerator)
```

- `systemError`
  [in]: Supplies an error code when a global error has occurred.
- `ppPlantObjectPropertyValueEnumerator`
  [in]: Points to an "IPlantObjectPropertyValueEnumerator" object that contains the enumeration of the process values of object instance properties.

Example

Copy code

```
void PlantObjectReadAsyncPropertySet(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"PlantModel"), &pUnk);
   IPlantModelPtr pPlantModel(pUnk);
   IPlantObjectPtr pPlantObject;
   CCfString strNode = L".hierarchy::PlantView/Unit1";
   //gets node for specified Node path
   errCode = pPlantModel->GetPlantObject(strNode.Get(), &pPlantObject);

   //empty property - so all node members should be read
   CCfVariant vtProperties;
   IPlantObjectPropertySetPtr pPlantObjectPropertySet;
   // get the PlantObject properties by property names
   pPlantObject->GetProperties(vtProperties, &pPlantObjectPropertySet);
   CPlantObjectPropertySetReadReply* pReply = new CPlantObjectPropertySetReadReply();
   IPlantObjectPropertySetReadReplyPtr pReadReply = pReply;
   // Read PlantObject properties values asynchronously
   pPlantObjectPropertySet->ReadAsync(pReadReply);
}
CFRESULT CFCALLTYPE CPlantObjectPropertySetReadReply::OnReadComplete(IN CFVARIANT
SystemError, IN IPlantObjectPropertyValueEnumerator* pPlantObjectPropertySet)
{
   uint32_t nCount = 0;
   pPlantObjectPropertySet->Count(&nCount);

   for (int i = 0;i < (int32_t)nCount; i++)
   {
      pPlantObjectPropertySet->MoveNext();
      IPlantObjectPropertyValue* pPlantModelPropertyValue;

      CCfString strName;
      pPlantModelPropertyValue->GetPlantObjectPropertyName(&strName);
      std::cout << "Name:" << strName.ToUTF8() << std::endl;
      int64_t qc;
      pPlantModelPropertyValue->GetQuality(&qc);
      std::cout << "Quality:" << qc << std::endl;
      int64_t ec;
      pPlantModelPropertyValue->GetError(&ec);
      std::cout << "Error:" << ec << std::endl;
      CCfDateTime64 dt;
      pPlantModelPropertyValue->GetTimeStamp(&dt);
      std::cout << "DateTime:" << dt.GetDateTimeString().ToUTF8() << std::endl;
      CCfVariant vtVal;
      pPlantModelPropertyValue->GetValue(&vtVal);
      std::cout << "Value:" << vtVal.uint64 << std::endl;
   }
   this->SetEvent();
   return CF_SUCCESS;
}
```

IPlantObjectPropertySetWriteReply

Description

The C++ interface "IPlantObjectPropertySetWriteReply" defines the "OnWriteComplete" method as callback method of a "WritedAsync" call. The method is used by the C++ interface "IPlantObjectPropertySet".

Members

The following methods are specified in the interface:

"OnWriteComplete" method

The "OnWriteComplete" callback method is called when the "WriteAsync" method is used.

```
CFRESULT OnWriteComplete(CFVARIANT
systemError, IPlantObjectPropertyValueEnumerator*
pPlantObjectPropertyValueEnumerator)P
```

- `systemError`
  [in]: Supplies an error code when a global error has occurred.
- `ppPlantObjectPropertyValueEnumerator`
  [in]: Points to an "IPlantObjectPropertyValueEnumerator" object that contains the enumeration of the process values of "IPlantObjectProperty" instances.

Example

Copy code

```
CFRESULT CFCALLTYPE CPlantObjectPropertySetWriteReply::OnWriteComplete(IN CFVARIANT
SystemError, IN IPlantObjectPropertyValueEnumerator* pPlantObjectPropertySet)
{
   uint32_t nCount = 0;
   pPlantObjectPropertySet->Count(&nCount);

   for (int i = 0;i < (int32_t)nCount; i++)
   {
      pPlantObjectPropertySet->MoveNext();
      IPlantObjectPropertyValue* pPlantModelPropertyValue;
      CCfString strName;
      pPlantModelPropertyValue->GetPlantObjectPropertyName(&strName);
      std::cout << "Name:" << strName.ToUTF8() << std::endl;
      int64_t ec;
      pPlantModelPropertyValue->GetError(&ec);
      std::cout << "Error:" << ec << std::endl;
   }

   this->SetEvent();
   return CF_SUCCESS;
}
```

IPlantObjectEnumerator

Description

The "IPlantObjectEnumerator" interface is a C++ interface that specifies methods for handling the enumeration of object instances of the plant model of a Runtime system.

All the methods return CF_SUCCESS following successful execution.

The interface inherits from the "ICfDispatch" interface.

Members

The following methods are specified in the interface:

"Current" method

Supplies the current element of the enumeration.

```
CFRESULT Current(IPlantObject **ppItem)
```

- `ppItem`
  [out]: Points to the current "IPlantObject" object as an element of the list.

"MoveNext" method

Move to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Reset" method

Resets the current position in the enumeration to the first element.

```
CFRESULT Reset()
```

"MoveNext" then supplies the first element of the enumeration.

"Count" method

Output the size of the enumeration or the number of elements in an enumeration.

```
CFRESULT Count(uint32_t *pValue)
```

- `value`
  [out]: Points to the value for the number of elements in the enumeration.

Example

Copy code

```
void PlantObjectCurrentViewPath(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"PlantModel"), &pUnk);
   IPlantModelPtr pPlantModel(pUnk);
   IPlantObjectEnumeratorPtr pPlantObjectEnum;
   CCfString str1 = L"NumberOfNodes";
   CCfString str2 = L"Quality";
   CCfString str3 = L"Quantity";
   CCfString str4 = L"DateActivation";
   CCfSafeArray daSafeArray(CF_VT_STR, 1U, 4U);
   int32_t index = 0;
   daSafeArray.PutElement(&index, (void*)&str1);
   ++index;
   daSafeArray.PutElement(&index, (void*)&str2);
   ++index;
   daSafeArray.PutElement(&index, (void*)&str3);
   ++index;
   daSafeArray.PutElement(&index, (void*)&str4);
   CCfVariant vtProperties;
   daSafeArray.Detach(&vtProperties);
   // gets PlantObjects for specified filter
   pPlantModel->GetPlantObjectsByExpression(vtProperties,
CCfString(L"UNIT").Get(), CCfString(L""),
CCfString(L"RUNTIME_1.hierarchy::PlantView/Unit1").Get(),
&pPlantObjectEnum);

   pPlantObjectEnum->MoveNext();
   IPlantObject* pPlantObject;
   while (CF_SUCCEEDED(pPlantObjectEnum->Current(&pPlantObject)))
   {
      DisplayNodeInfo(pPlantObject);
      pPlantObjectEnum->MoveNext();
   }
}
```

IPlantObjectAlarmSubscription

Description

The C++ interface "IPlantObjectAlarmSubscription" specifies methods for starting and stopping an "AlarmSubscription".

The interface inherits from the "ICfDispatch" interface.

Members

The following methods are specified in the interface:

"Start" method

Subscribe systems for monitoring changes of active alarms.

```
CFRESULT Start(IPlantObjectAlarmSubscriptionCallback* callbackPtr)
```

- `callbackPtr`
  [in]: Points to the "IPlantObjectAlarmSubscriptionCallback" object that implements the callback interface of the change monitoring.

"Stop" method

Clear monitoring of active alarms.

```
CFRESULT Stop(void)
```

"GetFilter" method

Supplies the string by which the result set is filtered.

```
CFRESULT GetFilter(CFSTR* filter)
```

- `filter`
  [out]: SQL-type string for filtering the result set of active alarms.

"SetFilter" method

Sets the string for filtering the result set of active alarms.

```
CFRESULT SetFilter(IN CFSTR filter)
```

- `filter`
  [in]: SQL-type string for filtering the result set of active alarms.
  All properties of an alarm can be used in the filter string. The filter string can contain operators. Refer to the section Syntax of the alarm filter (Page 7828).

"GetLanguage" method

Supplies the country identifier of the language of the monitored alarms.

```
CFRESULT GetLanguage(uint32_t* language)
```

- `language`
  [out]: Code of the country identification. See also sectionLocale IDs of the supported languages (Page 7829).

"SetLanguage" method

Sets the country identifier of the language of the monitored alarms.

```
CFRESULT SetLanguage)(uint32_t language)
```

- `language`
  [in]: Code of the country identification See also sectionLocale IDs of the supported languages (Page 7829).

"GetIncludeChildren" method

Supplies the setting for the child instances.

```
CFRESULT GetIncludeChildren(CFBOOL* bIsIncludeChildren)
```

- `bIsIncludeChildren`
  [out]: Reads out whether the child instances are part of monitoring.

"SetIncludeChildren" method

Determines the setting for the child instances.

```
CFRESULT SetIncludeChildren(CFBOOL bIsIncludeChildren)
```

- `bIsIncludeChildren`
  [in]: Controls whether the child instances are part of monitoring.

Example

Copy code

```
void PlantObjectSubscription(IRuntimePtr pRuntime)
{
   ICfUnknownPtr pUnk;
   pRuntime->GetObject(CCfString(L"PlantModel").Get(), &pUnk);

   IPlantModelPtr pPlantModel(pUnk);
   CPlantModelAlarmValue* pAlarmValue = new CPlantModelAlarmValue();
   pAlarmValue->AddRef();
   IPlantObjectAlarmCallback *pCB = pAlarmValue;
   CCfString strNode = L".hierarchy::RootNodeName/Node1";
   IPlantObjectPtr pPlantObject;
   pPlantModel->GetPlantObject(strNode.Get(), &pPlantObject);
   CCfSmartString daFilter;//= L"AlarmClassName = 'Alarm'";
   uint32_t daLanguage = 1033;
   IPlantObjectAlarmSubscriptionPtr pPlantObjectAlarmSubscription;
   pPlantObject->CreateAlarmSubscription(&pPlantObjectAlarmSubscription);
   pPlantObjectAlarmSubscription->SetFilter(daFilter.AllocCFSTR());
   pPlantObjectAlarmSubscription->SetLanguage(1033);
   pPlantObjectAlarmSubscription->SetFilter(false);
   pPlantObjectAlarmSubscription->SetIncludeChildren(false);
   CCfRefPtr<CPlantObjectAlarmSubscriptionCallback> pCallback = new
CPlantObjectAlarmSubscriptionCallback();
   pPlantObjectAlarmSubscription->Start(pCallback);
   if (0 == pCallback->WaitForcompletion(30000))
   {
      pPlantObjectAlarmSubscription->Stop();
   }
}
```

IPlantObjectAlarmCallback

Description

The C++ interface "IPlantObjectAlarmCallback" defines the callback method "OnAlarm".

Member

The following methods are defined in the interface:

"OnAlarm" method

Specifies the signature of the event handling method for the "OnAlarm" event of an "IPlantObject" instance.

```
OnAlarm(uint32_t systemError,
        CFSTR systemName,

Siemens::Runtime::HmiUnified::Alarms::IAlarmResultEnumerator*
pItems,
        CFBOOL completed)
```

- `systemError`
  Supplies an error code when a global error has occurred. When the error code is set, `pItems` is irrelevant.
- `systemName`
  Name of the runtime system that is subscribed for alarm monitoring by the user.
- `pItems`
  Supplies a pointer to "IAlarmResultEnumerator" that can be used to enumerate the active alarms.
- `completed`
  Status of the asynchronous transfer:
  - `True`: All alarms are read out.
  - `False`: Not all alarms are read out yet.

Example

Copy code

```
// Callback for alarm notifications
CFRESULT CFCALLTYPE CPlantModelAlarmValue::OnAlarm( uint32_t systemError, CFSTR
systemName, Siemens::Runtime::HmiUnified::Alarms::IAlarmResultEnumerator* pItems, CFBOOL
completed)
{
   CFRESULT hr = CF_FALSE;
   if (!completed)
   {
      uint32_t nsize;
      pItems->Count(&nsize);
      if (nsize > 0 && CF_SUCCEEDED(systemError)) {
      {
         int index = 0;
         while (CF_SUCCEEDED(pItems->MoveNext()))
         {
            IAlarmResultPtr ppValues;
            pItems->Current(&ppValues);

            CCfString strId;
            ppValues->GetSourceID(&strId);
            std::cout << "String ID = " << strId.ToUTF8().c_str() << std::endl;
            CCfString strName;
            ppValues->GetName(&strName);
            std::cout << "Name = " << strName.ToUTF8().c_str() << std::endl;
            CCfString strClassName;
            ppValues->GetAlarmClassName(&strClassName);
           std::cout << "Alarm Class Name = " << strClassName.ToUTF8().c_str() << std::endl;
            index++;
         }
      }
   }
   hr = CF_SUCCESS;
   return hr;
}
```

IPlantObjectAlarmSubscriptionCallback

Description

The C++ interface "IPlantObjectAlarmCallbackSubscription" defines the callback method "OnAlarm".

The interface inherits the "ICfUnknown" interface.

Members

The following methods are specified in the interface:

"OnAlarm" method

Specifies the signature of the event handling method for the "OnAlarm" event of an "IPlantObject" instance.

```
OnAlarm(uint32_t systemError,
        CFSTR systemName,

Siemens::Runtime::HmiUnified::Alarms::IAlarmResultEnumerator*
pItems)
```

- `systemError`
  Supplies an error code when a global error has occurred. When the error code is set, `pItems` is irrelevant.
- `systemName`
  Name of the runtime system that is subscribed for alarm monitoring by the user.
- `pItems`
  - Supplies a pointer to "IAlarmResultEnumerator" that can be used to enumerate the active alarms.

20.3.9.7 Interfaces of the Calendar option

ISHCCalendarOption

Description

The C++ interface "ISHCCalendarOption" specifies the "GetObject" method. The method supplies the calendar object of an "IPlantObject" instance. A calendar is always integrated via an "IPlantObject" instance.

Members

"GetObject" method

Supplies an error code of the type `CFRESULT`.

```
CFRESULT
GetObject(Siemens::Runtime::HmiUnified::PlantModel::IPlantObject *
pCpmNode, CFSTR objectName, ICfUnknown** ppObject)
```

- `cpmNode`
  [in]: Reference to the "IPlantObject" instance currently selected in the hierarchy
- `objectName`
  [in]: The name of the "IPlantObject" instance
- `ppObject`
  [out]: Returns an object of the type "ICfUnknown". The object is cast to a calendar object using the "QueryInterface" method.
  Example:

```
ISHCCalendarOptionPtr pShcOption;
pRuntime->GetOption(CCfString(ODK_SHC_OPTION),
(IOption**)&pShcOption);
ICfUnknownPtr pUnk;
pShcOption->GetObject(pPlantObject, ODK_SHC_CALENDAR, &pUnk);
ISHCCalendarPtr pCal;
pUnk->QueryInterface(IID_ISHCCalendar, (ICfUnknown**)&pCal);
COdkShcSample Sample;
Sample.SetCalendar(pCal);
```

Example

The following example serves as a basis for the other examples for the C++ interfaces of the Calendar option.

It shows how you can obtain the "IPlantObject" instance and also an "ISHCCalendar" instance. The "ISHCCalendar" instance referenced via `pCalendar` is also used in the other examples.

Copy code

```
#include <iostream>
#include "IOdkShcInterface.h"
#include "IOdkRt.h"
#include "IOdkRtAlarm.h"
using namespace Siemens::Runtime::HmiUnified::Rt;
using namespace Siemens::Runtime::HmiUnified::Common;
using namespace Siemens::Runtime::HmiUnified::PlantModel;
IRuntimePtr pRuntime;
ISHCCalendarPtr pCalendar;
ISHCCalendarSettingsProviderPtr pCalendarProvider;
ISHCCategoryProviderPtr pShcCategoryProvider;
ISHCShiftTemplatesProviderPtr pShcShiftTemplateProvider;
ISHCDayProviderPtr pShcDayProvider;
ISHCDayTemplatesProviderPtr pShcDayTemplateProvider;
ISHCActionTemplatesProviderPtr pShcActionTemplateProvider;
CCfString projectName = L"";
if (CF_SUCCEEDED(Connect(projectName, &pRuntime)))
{
     ICfUnknownPtr pPlantModelUnk;
     pRuntime->GetObject(CCfString(L"PlantModel"), &pPlantModelUnk);
     IPlantObjectPtr pPlantObject;
     IPlantModelPtr pPlantModel(pPlantModelUnk);
     CCfString strNode = L".hierarchy::Plant/Unit1";
     //gets Object for specified Node path
     pPlantModel->GetPlantObject(strNode.Get(), &pPlantObject);
     IOptionPtr pOdkOption;
     pRuntime->GetOption(CCfString(ODK_SHC_OPTION), &pOdkOption);
     ISHCCalendarOptionPtr pShcOption;
     pOdkOption->QueryInterface(IID_ISHCCalendarOption, (ICfUnknown**)&pShcOption);
     ICfUnknownPtr pUnk;
     pShcOption->GetObject(pPlantObject, ODK_SHC_CALENDAR, &pUnk);
     pUnk->QueryInterface(IID_ISHCCalendar, (ICfUnknown**)&pCalendar);
     // Get all data provider
     pCalendar->GetActionTemplatesProvider(&pShcActionTemplateProvider);
     pCalendar->GetCategoryProvider(&pShcCategoryProvider);
     pCalendar->GetDayProvider(&pShcDayProvider);
     pCalendar->GetDayTemplateProvider(&pShcDayTemplateProvider);
     pCalendar->GetShiftTemplateProvider(&pShcShiftTemplateProvider);
     pCalendar->GetSettings(&pCalendarProvider);
}
```

ISHCCalendar

Description

The C++ interface "ISHCCalendar" specifies the methods of a calendar.

The interface inherits from the "ICfUnknown" interface.

Members

"GetSettings" method

Supplies the "ISHCCalendarSettings" instances of the calendar.

```
CFRESULT GetSettings(ISHCCalendarSettings** calendar)
```

- `calendar`
  [out]: The "ISHCCalendarSettings" instance

"GetCategoryProvider" method

Supplies an "ISHCCategoryProvider" instance. The provider enables access to the "ISHCategory" instances of the calendar.

```
CFRESULT GetCategoryProvider(ISHCCategoryProvider**
ppCatgoryProvider)
```

- `ppCatgoryProvider`
  [out]: The "ISHCCategoryProvider" instance

"GetShiftTemplateProvider" method

Supplies an "ISHCShiftTemplatesProvider" instance. The provider enables access to the "ISHCShiftTemplate" instances of the calendar.

```
CFRESULT GetShiftTemplateProvider(ISHCShiftTemplatesProvider**
ppShiftTemplateProvider)
```

- `ppShiftTemplateProvider`
  [out]: The "ISHCShiftTemplatesProvider" instance

"GetDayTemplateProvider" method

Supplies an "ISHCDayTemplatesProvider" instance. The provider enables access to the "ISHCShiftTemplate" instances of the calendar.

```
CFRESULT GetDayTemplateProvider(ISHCDayTemplatesProvider**
ppDayTemplateProvider)
```

- `ppDayTemplateProvider`
  [out]: The "ISHCDayTemplatesProvider" instance

"GetActionTemplatesProvider" method

Supplies an "ISHCActionTemplatesProvider" instance. The provider enables access to the "ISHCActionTemplate" instances of the calendar.

```
CFRESULT GetActionTemplatesProvider)(OUT
ISHCActionTemplatesProvider** ppActionTemplatesProvider)
```

- `ppActionTemplatesProvider`
  [out]: The "ISHCActionTemplatesProvider" instance

"GetDayProvider" method

Supplies an "ISHCDayProvider" instance. The provider enables access to the "ISHCDay" instances of the calendar.

```
CFRESULT GetDayProvider(ISHCDayProvider** ppDayProvider)
```

- `ppDayProvider`
  [out]: The "ISHCDayProvider" instance

"GetObject" method

Creates an instance of the type defined in `value` and supplies a reference to the instance.

```
CFRESULT GetObject(const CFSTR value, ICfUnknown** ppObject)
```

- `value`
  [in]: Possible values:
  - "ODK_SHC_OPTION"
  - "ODK_SHC_CALENDAR"
  - "ODK_SHC_TIME_SLICE"
  - "ODK_SHC_DAY_TEMPLATE"
  - "ODK_SHC_DAY"
  - "ODK_SHC_DAY_TEMPLATE"
  - "ODK_SHC_ACTION_TEMPLATE"
  - "ODK_SHC_ACTION_TEMPLATE_ELEMENT"
- `ppObject`
  [out]: Reference to an object of the type "ICfUnknown", which can be cast to the corresponding type.
  Example:

```
ICfUnknownPtr pUnk;
ISHCShiftTemplatePtr pShcShiftTemplate;
pCalendar->GetObject(ODK_SHC_SHIFT_TEMPLATE, &pUnk);
pShcShiftTemplate = (ISHCShiftTemplatePtr)pUnk;
```

ISHCCalendarSettings

Description

The C++ interface "ISHCCalendarSettings" specifies methods for the calendar settings of an "ISHCCalendar" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"GetPlantObject" method

Supplies the name of the "IPlantObject" instance to which the calendar belongs.

```
GetPlantObject(CFSTR* pCpmNode)
```

- `pCpmNode`
  [out]: The name of the "IPlantObject" instance

"GetFirstDayOfWeek" method

Supplies the first day of the week.

```
CFRESULT GetFirstDayOfWeek(CFENUM * pvarRet)
```

- `pvarRet`
  Points to the enumeration "ShcWeekDay", which can contain the following values:
  - Sunday (0)
  - Monday (1)
  - Tuesday (2)
  - Wednesday (3)
  - Thursday (4)
  - Friday (5)
  - Saturday (6)

"GetFirstWeekOfYear" method

Supplies the first week of the year.

```
CFRESULT GetFirstWeekOfYear(CFENUM * pvarRet)
```

- `pvarRet`
  [out]: Points to the enumeration "ShcWeekStart", which can contain the following values:
  - FirstOfJanuary (0): The first week starts on the first of January.
  - AtLeastFourDays (1): The first week must have at least four days.
  - WholeWeek (2): The first week must have at least seven days.

"GetFiscalYearStartDay" method

Supplies the first day of the fiscal year.

```
CFRESULT GetFiscalYearStartDay(uint8_t* pvarRet)
```

- `pvarRet`
  [out]: The first day of the fiscal year of the calendar.

"GetFiscalYearStartMonth" method

Supplies the first month of the fiscal year.

```
CFRESULT GetFiscalYearStartMonth(uint8_t* pvarRet)
```

- `pvarRet`
  [out]: The first month of the fiscal year of the calendar.

"GetDayOffset" method

Supplies the offset with which the workday begins, calculated from midnight.

```
CFRESULT GetDayOffset(CFTIMESPAN64 * pvarRet)
```

- `pvarRet`
  [out]: Supplies the number of hours after midnight with which the day begins.

"GetWorkDays" method

Supplies the workdays of the calendar.

```
CFRESULT GetWorkDays(uint8_t* pvarRet)
```

- `pvarRet`
  [out]: The workdays of the calendar.

"GetTimeZone" method

Supplies the time zone of the calendar.

```
CFRESULT GetTimeZone(uint32_t* pTimeZone)
```

- `pvarRet`
  [out]: The time zone ID of Microsoft.

ISHCCategory

Description

The C++ interface "ISHCCategory" specifies the methods of a time category of an "ISHCCalendar" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"GetName" method

Supplies the name of the "ISHCCategory" instance.

```
CFRESULT GetName(CFSTR * pvarRet)
```

- `pvarRet`
  [out]: The name

"GetDescriptions" method

Supplies a map with the descriptions of the "ISHCCategory" instance and their language code IDs.

```
CFRESULT GetDescriptions(OUT ICfMapIDToVariant** ppDisplayNames)
```

- `ppDisplayNames`
  [out]: A map with int32/string pairs (language code ID for description).

Example:

```
ICfMapIDToVariantPtr pDescriptions;
hr = pShcCategory->GetDescriptions(&pDescriptions);
std::cout << "Descriptions::" << std::endl << std::endl;
uint32_t nCount2 = 0;
pDescriptions->Count(&nCount2);
for (uint32_t nIndex2 = 0; nIndex2 < nCount2; nIndex2++)
{
   int32_t nLanguageID;
```

```
   pDescriptions->KeyAt(nIndex2, &nLanguageID);
   CCfVariant strDescription;
   pDescriptions->ValueAt(nLanguageID, &strDescription);
   std::cout << "LangauageID =" << nLanguageID << " Description="
<< CCfSmartString(strDescription).ToUTF8().c_str() << std::endl;
}
```

"GetDisplayNames" method

Supplies a map with the display names of the "ISHCCategory" instance and their language code IDs.

```
CFRESULT GetDisplayNames(ICfMapIDToVariant** ppDisplayNames)
```

- `ppDisplayNames`
  [out]: A map with int32/string pairs (language code ID for display name).

Example: Similar to "GetDescriptions"

"GetColor" method

Supplies the color of the "ISHCCategory" instance.

```
CFRESULT GetColor(uint32_t* pColor)
```

- `pColor`
  [out]: Returns a 4-byte value for an RGBA color value.

"GetIsDeleted" method

Supplies the information on whether the "ISHCCategory" instance was deleted in Engineering.

```
CFRESULT GetIsDeleted(CFBOOL* p_bIsDeleted) = 0;
```

- `p_bIsDeleted`
  [out]:
  - 0: Was not deleted (default)
  - 1: Was deleted

See also

Locale IDs of the supported languages (Page 7829)

ISHCCategoryEnumerator

Description

The C++ interface "ISHCCategoryEnumerator" specifies methods for handling the enumeration of the time categories of an "ISHCCalendar" instance. The enumeration is returned by the `Read` method of an "ISHCCategoryProvider" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(ISHCCategory** ppItem)
```

- `ppItem`
  [out]: The current "ISHCCategory" instance

"Reset" method

Reset the current position in the enumeration. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumeration or the number of its elements.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of categories

Example

Copy code

```
void PrintCategory(const ISHCCategoryEnumeratorPtr& p_pShcCategoryEnum)
{
   uint32_t nCount = 0;
   p_pShcCategoryEnum->Count(&nCount);
   for (uint32_t nIndex = 0; nIndex < nCount; nIndex++)
   {
      p_pShcCategoryEnum->MoveNext();

         std::cout << "LangauageID =" << nLanguageID << " Description=" <<
CCfSmartString(strDescription).ToUTF8().c_str() << std::endl;
      }
   }
}
```

ISHCCategoryProvider

Description

The C++ interface "ISHCCategoryProvider" provides you with read access to an "ISHCCategoryEnumerator" instance which contains an enumeration with the time categories of an "ISHCCalendar" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"Browse" method

Supplies an "ISHCCategoryEnumerator" instance which has access to an enumeration with the "ISHCCategory" instances of the calendar.

```
CRFESULT Browse(ISHCCategoryEnumerator** data)
```

- `data`
  [out]: The enumerator

Example:

```
ISHCCategoryEnumeratorPtr pShcCategoryEnum;
CFRESULT hr = pShcCategoryProvider->Browse(&pShcCategoryEnum);
if (CF_SUCCEEDED(hr))
    PrintCategory(pShcCategoryEnum);
```

ISHCTimeSlice

Description

The C++ interface "ISHCTimeSlice" specifies the methods of a time slice.

The interface inherits from the "ICfUnknown" interface.

Members

"GetStartTime" method

Returns the start time of the "ISHCTimeSlice" instance.

```
CFRESULT GetStartTime(CFDATETIME64* pStartTime)
```

- `pStartTime`
  [out]: Time stamp with the start time of the time slice

"GetDuration" method

Supplies the duration of the "ISHCTimeSlice" instance.

```
CFRESULT GetDuration(CFTIMESPAN64* pDuration)
```

- `pDuration`
  [out]: The duration of the time slice

"GetCategory" method

Returns the time category time of the "ISHCTimeSlice" instance.

```
CFRESULT GetCategory(CFSTR* pstrCategoryName)
```

- `pstrCategoryName`
  [out]: The name of the time category

"SetCategory" method

Sets the time category of the "ISHCTimeSlice" instance.

```
CFRESULT SetCategory(CFSTR pstrCategoryName)
```

- `pstrCategoryName`
  [in]: The name of the new time category.

"SetStartTime" method

Sets the start time of the "ISHCTimeSlice" instance.

```
CFRESULT SetStartTime(CFDATETIME64 startTime)
```

- `startTime`
  [in]: The new start time of the time slice.

"SetDuration" method

Sets the duration of the "ISHCTimeSlice" instance.

```
CRFESULT SetDuration(CFTIMESPAN64 duration)
```

- `duration`
  [in]: The new duration of the time slice

ISHCTimeSliceEnumerator

Description

The C++ interface "ISHCTimeSliceEnumerator" specifies methods for handling the enumeration of the time slices of an "ISHCShiftTemplate" instance or "ISHCShift" instance.

The enumeration is returned by the `Read` method of these instances.

The interface inherits from the "ICfUnknown" interface.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(ISHCTimeSlice** ppItem)
```

- `ppItem`
  [out]: The current "ISHCTimeSlice" instance

"Reset" method

Reset the current position in the enumeration. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumeration or the number of its elements.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of time slices

Example

Copy code

```
void printTimeSlice(const ISHCTimeSliceEnumeratorPtr& p_pShcTimeSliceEnum)
{
   uint32_t nCout = 0;
   p_pShcTimeSliceEnum->Count(&nCout);
   for (uint32_t nIndex = 0; nIndex < nCout; nIndex++)
   {
      p_pShcTimeSliceEnum->MoveNext();
      cout << endl;
      ISHCTimeSlicePtr pTimeSlice;
      p_pShcTimeSliceEnum->Current(&pTimeSlice);
      CCfString strCategoryName;
      pTimeSlice->GetCategory(&strCategoryName);
      std::cout << "Category= " << strCategoryName.ToUTF8().c_str() << std::endl;
      CCfTimeSpan64 tsDuration;
      pTimeSlice->GetDuration(&tsDuration);
      CCfString strDuration = tsDuration.GetTimeSpanString();
      std::cout << "Durations= " << strDuration.ToUTF8().c_str() << std::endl;
      CCfDateTime64 dtStartTime;
      pTimeSlice->GetStartTime(&dtStartTime);
      CCfString strStarttime = dtStartTime.GetDateTimeString(false);
      std::cout << "Start Time= " << strStarttime.ToUTF8().c_str() << std::endl;
   }
}
```

ISHCDay

Description

The C++ interface "ISHCDay" specifies the methods of a day.

The interface inherits from the "ICfUnknown" interface.

Members

"CreateShift" method

Returns a new "ISHCShift" instance.

```
CRFESULT CreateShift(ISHCShiftTemplate* pShiftTemplate,
CFTIMESPAN64 startTime, ISHCShift** pShift)
```

- `pShiftTemplate`
  [in]: The "ISHCShiftTemplate" instance on which the new shift is to be based.
- `startTime`
  [in]: Time stamp for the start time of the new shift.
- `pShift`
  [out]: The new shift

"DeleteShift" method

Deletes an "ISHCShift" instance.

```
CRFESULT DeleteShift(ISHCShift* pShift)
```

- `pShift`
  [in]: Reference to the shift to be deleted.

"GetShifts" method

Supplies an "ISHCShiftEnumerator" instance via which you access the "ISHCShift" instances of the "ISHCDay" instance.

```
CRFESULT GetShifts(ISHCShiftEnumerator** ppSHCShiftEnumerator)
```

- `ppSHCShiftEnumerator`
  [out]: The enumerator with which you access the shifts of the "ISHCDay" instance. The shifts are contained in an array.

"GetComments" method

Supplies a map with the comments of the "ISHCDay" instance and their language code IDs.

```
CRFESULT GetComments(ICfMapIDToVariant** ppComments)
```

- `ppComments`
  [out]: A map with int32/string pairs (language code ID for comment).

Example:

```
ICfMapIDToVariantPtr pComments;
pShcshift->GetComments(&pComments);
uint32_t nCount = 0;
pComments->Count(&nCount);
for (uint32_t nIndex1 = 0; nIndex1 < nCount; nIndex1++)
{
   int32_t nLanguageID;
   pComments->KeyAt(nIndex1, &nLanguageID);
   CCfVariant strComments;
   pComments->ValueAt(nLanguageID, &strComments);
   std::cout << "LangauageID =" << nLanguageID << " Comments=" <<
CCfSmartString(strComments).ToUTF8().c_str() << std::endl;
```

```
}
```

"SetComments" method

Adds a new comment in the specified language to the "ISHCDay" instance.

```
CRFESULT SetComment(CFLCID languageId , CFSTR pComments)
```

- `languageId`
  [in]: The language code ID
- `pComments`
  [in]: The comment text

"GetStartTime" method

Returns the start time of the "ISHCDay" instance.

```
CRFESULT GetStartTime(CFDATETIME64* pStartTime)
```

- `pStartTime`
  [out]: The start time

"SetStartTime" method

Sets the start time of the "ISHCDay" instance.

```
CRFESULT SetStartTime(CFDATETIME64 startTime)
```

- `startTime`
  [in]: The new start time

"GetIsCustomized" method

Supplies the information on whether the "ISHCDay" instance was edited by users.

```
CRFESULT GetIsCustomized)(CFBOOL* pIsCustomized)
```

- `pIsCustomized`
  [out]:
  - 0: Was not processed
  - 1: Was processed

"GetDayTemplate" method

Supplies the "ISHCDayTemplate" instance on which the "ISHCDay" instance is based.

```
CRFESULT GetDayTemplate(CFSTR* pDayTemplate)
```

- `pDayTemplate`
  [out]: The day template

"SetDayTemplate" method

Sets the "ISHCDayTemplate" instance of the "ISHCDay" instance.

```
CRFESULT SetDayTemplate(CFSTR pDayTemplate)
```

- `pDayTemplate`
  [in]: The new day template

ISHCDayEnumerator

Description

The C++ interface "ISHCDayEnumerator" specifies methods for handling the enumeration of the days of an "ISHCCalendar" instance. The enumeration is returned by the "Read" method of an "ISHCDayProvider" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(ISHCTimeSlice** ppItem)
```

- `ppItem`
  [out]: The current "ISHCDay" instance

"Reset" method

Reset the current position in the enumeration. The "MoveNext" method moves afterwards to the first element.

"Count" method

Output the size of the enumeration or the number of its elements.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of days

Example

Copy code

```
void PrintDay(const ISHCDayEnumeratorPtr& p_pShcdayEnum)
{
   uint32_t nCount = 0;
   p_pShcdayEnum->Count(&nCount);
   for (uint32_t nIndex = 0; nIndex < nCount; nIndex++)
   {
      cout << endl;
      p_pShcdayEnum->MoveNext();
      ISHCDayPtr pShcday;
      p_pShcdayEnum->Current(&pShcday);
      CCfString strDaytemplate;
      pShcday->GetDayTemplate(&strDaytemplate);
      cout << "DayTemplate= " << strDaytemplate.ToUTF8().c_str() << endl;

      ICfMapIDToVariantPtr pComments;
      pShcday->GetComments(&pComments);
      std::cout << "comments:-" << std::endl << std::endl;
      uint32_t nCount1 = 0;
      pComments->Count(&nCount1);
      for (uint32_t nIndex1 = 0; nIndex1 < nCount1; nIndex1++)
      {
         int32_t nLanguageID;
         pComments->KeyAt(nIndex1, &nLanguageID);
         CCfVariant strComments;
         pComments->ValueAt(nLanguageID, &strComments);
         std::cout << "LangauageID = " << nLanguageID << " Comments= " <<
CCfSmartString(strComments).ToUTF8().c_str() << std::endl;
      }
      CFBOOL bIsCustomized;
      pShcday->GetIsCustomized(&bIsCostomized);
      cout << "IsCustomized=" << (uint32_t)bIsCostomized << endl;
      CCfDateTime64 dtStartTime;
      pShcday->GetStartTime(&dtStartTime);
      cout << "StartTime= " << dtStartTime.GetDateTimeString(false).ToUTF8().c_str() <<
endl;

      ISHCShiftEnumeratorPtr pDayShifts;
      pShcday->GetShifts(&pDayShifts);
      //printShift(pDayShifts);
      uint32_t nCout = 0;
      pDayShifts->Count(&nCout);
      for (uint32_t nIndex = 0; nIndex < nCout; nIndex++)
      {
         cout << endl;
         pDayShifts->MoveNext();
         ISHCShiftPtr pShcshift;
         pDayShifts->Current(&pShcshift);
         CCfString strshiftTemplateName;
         pShcshift->GetShiftTemplate(&strshiftTemplateName);
         std::cout << "ShiftTemplateName= " << strshiftTemplateName.ToUTF8().c_str() <<
std::endl;
         CCfTimeSpan64 tsDuration;
         pShcshift->GetDuration(&tsDuration);
         CCfString strDuration = tsDuration.GetTimeSpanString();
```

Copy code

```
         std::cout << "Durations= " << strDuration.ToUTF8().c_str() << std::endl;
         CFBOOL bIsCustomised;
         pShcshift->GetIsCustomized(&bIsCustomised);
         std::cout << "Is Customised= " << (uint32_t)bIsCustomised << std::endl;
         CFENUM ndeltaKind;
         pShcshift->GetDeltaKind(&ndeltaKind);
         std::cout << "deltaKind = " << ndeltaKind << std::endl;

            CCfString strStarttime = dtStartTime.GetDateTimeString(false);
            std::cout << "Start Time= " << strStarttime.ToUTF8().c_str() << std::endl;
         }
      }
   }
}
```

ISHCDayProvider

Description

The C++ interface "ISHCDayProvider" provides you with access to an "ISHCDayEnumerator" instance which contains an enumeration with the days of an "ISHCCalendar" instance. With the methods of the provider, you can create, read, update and delete days. The provider is returned by the "GetDayProvider" method of an "ISHCCalendar" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"Browse" method

Supplies an "ISHCDayEnumerator" instance which has access to an enumeration with the "ISHCDay" instances of a specific time period of the calendar.

```
CRFESULT Browse(CFDATETIME64 StartTime, CFDATETIME64 endTime,
ISHCDayEnumerator** ppISHCDayEnumerator)
```

- `startTime`
  [in]: Start time
- `endTime`
  [in]: End time
- `ppISHCDayEnumerator`
  [out]: The enumerator

Example:

Copy code

```
CCfTimeSpan64 Get1Hour()
{
     CCfDateTime64 dt = CCfDateTime64::Now(false);
     CFDATETIMEST st2;
     dt.GetDateTimeStruct(st2);
     st2.cHours = st2.cHours - 1;
     CCfDateTime64 dt2;
     dt2.SetFromDateTimeStruct(&st2);
     return dt.GetDifference(dt2);
}
CCfDateTime64 GetStartoftheDay()
{
     CCfDateTime64 dt = CCfDateTime64::Now(false);
     CFDATETIMEST st;
     dt.GetDateTimeStruct(st);
     st.cHours = 0;
     st.cMinutes = 0;
     st.cSeconds = 0;
     st.sHundredNanoSeconds = 0;
     st.sMicroSeconds = 0;
     st.sMilliSeconds = 0;
     dt.SetFromDateTimeStruct(&st);
     return dt;
}
ISHCDayEnumeratorPtr pDayEnum; // Get day instances for a timespan of three days
CFRESULT hr = pShcDayProvider->Browse(GetStartoftheDay() - (Get1Hour() * 24),
GetStartoftheDay() + (Get1Hour() * 48), &pDayEnum);
```

"Create" method

Adds new days to the enumeration with the "ISHCDay" instances of the calendar.

```
CFRESULT Create(ICfArrayIUnknown* pDays)i
```

- `pDays`
  [in]: An array with the days to be added.

Example:

Copy code

```
void CreateDayWithShift()
{
   ISHCDayTemplateEnumeratorPtr pShcDayTemplates;
   CCfArrayIUnknown arrDays;
   ICfArrayIUnknownPtr pDays;
   m_pShcDayTemplateProvider->Browse(CF_FALSE, &pShcDayTemplates);
   uint32_t nCount = 0;
   pShcDayTemplates->Count(&nCount);
   pShcDayTemplates->MoveNext();
   ISHCDayTemplatePtr pShcDayTemplate;
   pShcDayTemplates->Current(&pShcDayTemplate);
   CCfString strDayTemplateName;
   pShcDayTemplate->GetName(&strDayTemplateName);
   ICfUnknownPtr pUnk;
   m_pCalendar->GetObject(ODK_SHC_DAY, &pUnk);
   ISHCDayPtr pShcDay = (ISHCDayPtr)pUnk;
   pShcDay->SetDayTemplate(strDayTemplateName);
   CCfDateTime64 dt = GetStartoftheDay();
   pShcDay->SetStartTime(dt);
   pShcDay->SetComment(1033, CCfString(L"DayComments"));
   arrDays.Append(pShcDay);
   arrDays.DetachEnumerator(&pDays);
   m_pShcDayProvider->Create(pDays);
   ISHCShiftTemplateEnumeratorPtr pShcShiftTemplateEnum;
   m_pShcShiftTemplateProvider->Browse(CF_FALSE, &pShcShiftTemplateEnum);
   pShcShiftTemplateEnum->MoveNext();
   ISHCShiftTemplatePtr pshcShiftTemplate;
   pShcShiftTemplateEnum->Current(&pshcShiftTemaplate);
   ISHCShiftPtr pShcdayShift;
   CCfTimeSpan64 starttime = Get1Hour() * 10;
   pShcDay->CreateShift(pshcShiftTemaplate, starttime, &pShcdayShift);
}
```

"Update" method

Updates "ISHCDay" instances of the enumeration.

`CRFESULTUpdate(ICfArrayIUnknown* pDays)`

- `pDays`
  [in]: An array with the days to be updated.

Example:

Copy code

```
void UpdateDayWithShift()
{
   ISHCDayEnumeratorPtr pDayEnum;
   m_pShcDayProvider->Browse(GetStartoftheDay() - (Get1Hour() * 24), GetStartoftheDay() +
(Get1Hour() * 24), &pDayEnum);
   pDayEnum->MoveNext();
   CCfArrayIUnknown ArrayDays;
   ICfArrayIUnknownPtr pArrayDays;
   ISHCDayPtr pShcDay;
   pDayEnum->Current(&pShcDay);
   CCfDateTime64 dt;
   pShcDay->GetStartTime(&dt);
   dt.AddTimeSpan(Get1Hour());
   pShcDay->SetStartTime(dt);//Update StartTime Not Supported
   pShcDay->SetComment(1033, CCfString(L"DayComment"));
   ISHCShiftEnumeratorPtr pShiftEnum;
   pShcDay->GetShifts(&pShiftEnum);
   pShiftEnum->MoveNext();
   ISHCShiftPtr pShcShift;
   pShiftEnum->Current(&pShcShift);
   CCfTimeSpan64 ts;
   pShcShift->GetDuration(&ts);
   pShcShift->SetDuration(ts + Get1Hour());
   pShcShift->SetComment(1033, CCfString(L"UpdatedShiftComments"));
   ArrayDays.Append(pShcDay);
   ArrayDays.DetachEnumerator(&pArrayDays);
   m_pShcDayProvider->Update(pArrayDays);
}
```

"Delete" method

Deletes "ISHCDay" instances of the calendar from the enumeration.

```
CRFESULT Delete(ICfArrayIUnknown* pActionTemplates)
```

- `pActionTemplates`
  [in]: An array with the days to be deleted.

Example:

Copy code

```
void DeleteDayWithShift()
{
   ISHCDayEnumeratorPtr pDayEnum;
   m_pShcDayProvider->Browse(GetStartoftheDay() - (Get1Hour() * 24), GetStartoftheDay() +
(Get1Hour() * 48), &pDayEnum);
   uint32_t nSize = 0;
   pDayEnum->Count(&nSize);
   CCfArrayIUnknown ArrayDays;
   ICfArrayIUnknownPtr pArrayDays;
   for (uint32_t nIdnex = 0;nIdnex < nSize;nIdnex++)
   {
      pDayEnum->MoveNext();
      ISHCDayPtr pShcDay;
      pDayEnum->Current(&pShcDay);
      ISHCShiftEnumeratorPtr pShiftEnum;
      pShcDay->GetShifts(&pShiftEnum);
      pShiftEnum->MoveNext();
      ISHCShiftPtr pShcShift;
      pShiftEnum->Current(&pShcShift);
      pShcDay->DeleteShift(pShcShift);
      ArrayDays.Append(pShcDay);
   }
   ArrayDays.DetachEnumerator(&pArrayDays);
   m_pShcDayProvider->Delete(pArrayDays);
}
```

ISHCDayTemplate

Description

The C++ interface "ISHCDayTemplate" specifies the methods of a day template.

The interface inherits from the "ICfUnknown" interface.

Members

"GetName" method

Supplies the name of the "ISHCDayTemplate" instance.

```
CFRESULT GetName(CFSTR * pvarRet)
```

- `pvarRet`
  [out]: The name of the day template

"SetName" method

Sets the name of the "ISHCDayTemplate" instance.

```
CRFESULT SetName(CFSTR  value)
```

"GetDisplayNames" method

Supplies a map with the display names of the "ISHCDayTemplate" instance and their language code IDs.

```
CFRESULT GetDisplayNames(ICfMapIDToVariant** ppDisplayNames)
```

- `ppDisplayNames`
  [out]: A map with int32/string pairs (language code ID for display name).

Example:

```
ICfMapIDToVariantPtr pDisplayNames;
pShcDayTemplate->GetDisplayNames(&pDisplayNames);
std::cout << "DisplayNames::" << std::endl << std::endl;
uint32_t nCount2 = 0;
pDisplayNames->Count(&nCount2);
for (uint32_t nIndex2 = 0; nIndex2 < nCount2; nIndex2++)
{
   int32_t nLanguageID;
   pDisplayNames->KeyAt(nIndex2, &nLanguageID);
   CCfVariant strDIsplayname;
   pDisplayNames->ValueAt(nLanguageID, &strDIsplayname);
   std::cout << "LangauageID =" << nLanguageID << " DisplayName="
<< CCfSmartString(strDIsplayname).ToUTF8().c_str() << std::endl;
}
```

"SetDisplayName" method

Adds a new display name in the specified language to the "ISHCDayTemplate" instance.

```
CRFESULT SetDisplayName(CFLCID languageId, CFSTR pDisplayName)
```

- `languageId`
  [in]: The language code ID
- `pDisplayName`
  [in]: The comment text

"GetDescriptions" method

Supplies a map with the descriptions of the "ISHCDayTemplate" instance and their language code IDs.

```
CFRESULT GetDescriptions(ICfMapIDToVariant** ppDisplayNames)
```

- `ppDisplayNames`
  [out]: A map with int32/string pairs (language code ID for description).

Example: Similar to "GetDescriptions" of "ISHCCategory".

"SetDescription" method

Adds a new description in the specified language to the "ISHCDayTemplate" instance.

```
CRFESULT SetDescription)(CFLCID languageId, CFSTR pDescriptions)
```

- `languageId`
  [in]: The language code ID
- `pDescriptions`
  [in]: The description text

"GetShifts" method

Supplies an "ISHCShiftEnumerator" instance. The enumerator provides you with access to the "ISHCShift" instances of the "ISHCDayTemplate" instance.

```
GetShifts(ISHCShiftEnumerator** ppSHCShiftEnumerator)
```

- `ppSHCShiftEnumerator`
  [out]: The enumerator

"CreateShift" method

Adds an "ISHCShift" instance to the "ISHCDayTemplate" instance.

```
CRFESULT CreateShift(ISHCShiftTemplate* pShiftTemplate,
CFTIMESPAN64 pStartTime, ISHCShift** pShift)
```

- `pShiftTemplate`
  [in]: Reference to the shift template on which the shift is based.
- `pStartTime`
  [in] Time stamp with the start time of the shift
- `pShift`
  [out] reference to the new shift

"DeleteShift" method

Deletes an "ISHCShift" instance of the "ISHCDayTemplate" instance.

```
CFRESULTDeleteShift(ISHCShift* pShift)
```

- `pShift`
  [in]: Reference to the shift to be deleted

"GetIsDeleted" method

Supplies the information on whether the "ISHCDayTemplate" instance was deleted by users.
`CFRESULT GetIsDeleted(CFBOOL* pIsDeleted)`

- `pIsDeleted`
  [out]:
  - 0: Was not deleted
  - 1: Was deleted

ISHCDayTemplatesProvider

Description

The C++ interface "ISHCDayTemplatesProvider" provides you with access to an "ISHCDayTemplateEnumerator" instance which contains an enumeration with the day templates of an "ISHCCalendar" instance. With the methods of the provider, you can create, read, update and delete day templates. The provider is returned by the "GetDayTemplateProvider" method of an "ISHCCalendar" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"Browse" method

Supplies an "ISHCDayTemplateEnumerator" instance which has access to an enumeration with the "ISHCDayTemplate" instances of the calendar.

```
CRFESULT Browse(CFBOOL includeDeleted, ISHCDayTemplateEnumerator**
ppISHCDayTemplateEnumerator)
```

- `includeDeleted`
  Saves whether the enumerator also has access to the deleted day templates.
- `ppISHCDayTemplateEnumerator`
  [out]: The enumerator

Example:

```
ISHCDayTemplateEnumeratorPtr pShcDayTemplates;
pShcDayTemplateProvider->Browse(CF_FALSE, &pShcDayTemplates);
```

"Create" method

Adds new "ISHCDayTemplate" instances to the enumeration with the"ISHCDayTemplate" instances of the calendar.

```
CRFESULTUpdate(ICfArrayIUnknown* pDayTemplates)
```

- `pDayTemplates`
  [in]: An array with the day templates to be added.

Example:

Copy code

```
void CreateDayTemplateWithShift()
{
   ICfUnknownPtr pUnk;
   m_pCalendar->GetObject(ODK_SHC_DAY_TEMPLATE, &pUnk);
   CCfArrayIUnknown ArrayTemplate;
   ICfArrayIUnknownPtr pArrayTemplate;
   ISHCDayTemplatePtr pShcDayTemplate = (ISHCDayTemplatePtr)pUnk;
   pShcDayTemplate->SetName(CCfString(L"DaytemplateName"));
   pShcDayTemplate->SetDisplayName(1033, CCfString(L"DayTemplateDisplayName"));
   pShcDayTemplate->SetDescription(1033, CCfString(L"DayTemplate Descriptions"));

   ArrayTemplate.Append(pShcDayTemplate);
   ArrayTemplate.DetachEnumerator(&pArrayTemplate);
   m_pShcDayTemplateProvider->Create(pArrayTemplate);
   ISHCShiftTemplateEnumeratorPtr pShcShiftTemplates;
   m_pShcShiftTemplateProvider->Browse(CF_FALSE, &pShcShiftTemplates);
   pShcShiftTemplates->MoveNext();
   ISHCShiftTemplatePtr pShcshiftTemplate;
   pShcShiftTemplates->Current(&pShcshiftTemplate);
   CCfString strShiftTemplateName;
   pShcshiftTemplate->GetName(&strShiftTemplateName);
   ISHCShiftPtr pShift;
   pShcDayTemplate->CreateShift(pShcshiftTemplate, Get1Hour() * 1, &pShift);
}
```

"Update" method

Updates "ISHCDayTemplate" instances of the enumeration.

```
CRFESULTUpdate(ICfArrayIUnknown* pDayTemplates)
```

- `pDayTemplates`
  [in]: An array with the day templates to be updated.

Example:

Copy code

```
void UpdateDayTemplateWithShift()
{
   ISHCDayTemplateEnumeratorPtr pShcDayTemplates;
   hr = m_pShcDayTemplateProvider->Browse(false, &pShcDayTemplates);
   CCfArrayIUnknown ArrayDayTemplate;
   ICfArrayIUnknownPtr pArrayDayTemplate;
   uint32_t nCount = 0;
   pShcDayTemplates->Count(&nCount);
   for (uint32_t i = 0; i < nCount; i++)
   {
      pShcDayTemplates->MoveNext();
      ISHCDayTemplatePtr pShcDayTemplate;
      pShcDayTemplates->Current(&pShcDayTemplate);
      pShcDayTemplate->SetName(CCfString(L"UpdatedDayTemplateName"));
      ISHCShiftEnumeratorPtr pShiftEnum;
      pShcDayTemplate->GetShifts(&pShiftEnum);
      uint32_t nlength = 0;
      pShiftEnum->Count(&nlength);
      for (uint32_t nIndex = 0; nIndex < nlenght; nIndex++)
      {
         pShiftEnum->MoveNext();
         ISHCShiftPtr pShcShift;
         pShiftEnum->Current(&pShcShift);
         ISHCTimeSliceEnumeratorPtr pShcTimeSliceEnum;
         pShcShift->GetTimeSlices(&pShcTimeSliceEnum);
         pShcShift->SetDuration(Get1Hour() * 8);
         pShcShift->SetComment(1033, CCfString("ShiftComment"));
         uint32_t nCount1 = 0;
         pShcTimeSliceEnum->Count(&nCount1);
         for (uint32_t nIndex1 = 0; nIndex1 < nCount1; nIndex1++)
         {
            pShcTimeSliceEnum->MoveNext();
            ISHCTimeSlicePtr pShctimeslice;
            pShcTimeSliceEnum->Current(&pShctimeslice);
            pShctimeslice->SetCategory(CCfString(L"Working"));
         }
         ArrayDayTemplate.Append(pShcDayTemplate);
   }
   ArrayDayTemplate.DetachEnumerator(&pArrayDayTemplate);
  m_pShcDayTemplateProvider->Update(pArrayDayTemplate);
}
```

"Delete" method

Deletes "ISHCDayTemplate" instances of the calendar from the enumeration.

```
CRFESULT Delete(ICfArrayIUnknown* pDayTemplates)
```

- `pDayTemplates`
  [in]: An array with the day templates to be deleted.

Example:

Copy code

```
void DeleteDaytemplateWithShift()
{
   ISHCDayTemplateEnumeratorPtr pShcDayTemplates;
   m_pShcDayTemplateProvider->Browse(CF_FALSE, &pShcDayTemplates);
   CCfArrayIUnknown ArrayDayTemplate;
   ICfArrayIUnknownPtr pArrayDayTemplate;
   uint32_t nCount = 0;
   pShcDayTemplates->Count(&nCount);
   for (uint32_t i = 0; i < nCount; i++)
   {
      pShcDayTemplates->MoveNext();
      ISHCDayTemplatePtr pShcDayTemplate;
      pShcDayTemplates->Current(&pShcDayTemplate);
      ISHCShiftEnumeratorPtr pShiftEnum;
      pShcDayTemplate->GetShifts(&pShiftEnum);
      uint32_t nlength = 0;
      pShiftEnum->Count(&nlength);
      for (uint32_t nIndex = 0; nIndex < nlenght; nIndex++)
      {
         pShiftEnum->MoveNext();
         ISHCShiftPtr pShcShift;
         pShiftEnum->Current(&pShcShift);
         pShcDayTemplate->DeleteShift(pShcShift);
      }
      ArrayDayTemplate.Append(pShcDayTemplate);

      ArrayDayTemplate.DetachEnumerator(&pArrayDayTemplate);
      m_pShcDayTemplateProvider->Delete(pArrayDayTemplate);
   }
}
```

ISHCShiftTemplate

Description

The C++ interface "ISHCShiftTemplate" specifies the methods of a shift template.

The interface inherits from the "ICfUnknown" interface.

Members

"GetName" method

Supplies the name of the "ISHCShiftTemplate" instance.

```
GetName(CFSTR * pvarRet)
```

- `pvarRet`
  [out]: Name

"SetName" method

Sets the name of the "ISHCShiftTemplate" instance.

```
CRFESULT SetName(CFSTR  value)
```

"GetDisplayNames" method

Supplies a map with the display names of the "ISHCShiftTemplate" instance and their language code IDs.

```
CFRESULT GetDisplayNames(ICfMapIDToVariant** ppDisplayNames)
```

- `ppDisplayNames`
  [out]: A map with int32/string pairs (language code ID for display name).

"SetDisplayName" method

Adds a new entry to a map with the display names of the "ISHCShiftTemplate" instance and their language code IDs.

```
CRFESULT SetDisplayName(CFLCID languageId, CFSTR pDisplayName)
```

- `languageId`
  [in]: The language code ID
- `pDisplayName`
  [in]: The comment text

"GetDescriptions" method

Supplies a map with the descriptions of the "ISHCShiftTemplate" instance and their language code IDs.

```
CFRESULT GetDescriptions(ICfMapIDToVariant** ppDisplayNames)
```

- `ppDisplayNames`
  [out]: A map with int32/string pairs (language code ID for description).

"SetDescription" method

Adds a new entry to a map with the description of the "ISHCShiftTemplate" instance and their language code IDs.

```
CRFESULT SetDescription(CFLCID languageId, CFSTR pDescriptions)
```

- `languageId`
  [in]: The language code ID
- `pDescriptions`
  [in]: The description text

"GetIsDeleted" method

Supplies the information on whether the "ISHCShiftTemplate" instance was deleted by users.

```
CFRESULT GetIsDeleted(CFBOOL* pIsDeleted)
```

- `pIsDeleted`
  [out]:
  - 0: Was not deleted
  - 1: Was deleted

"GetDuration" method

Supplies the duration of the "ISHCShiftTemplate" instance.

```
CFRESULT GetDuration(CFTIMESPAN64* pDuration)
```

- `pDuration`
  [out]: The duration of the shift template

"SetDuration" method

Sets the duration of the "ISHCShiftTemplate" instance.

```
CFRESULT SetDuration(CFTIMESPAN64 duration)
```

- `duration`
  [in]: The duration of the shift template

"GetTimeSlices" method

Supplies an "ISHCTimeSliceEnumerator" instance. The enumerator provides you with access to the "ISHCTimeSlice" instances of the "ISHCShiftTemplate" instance.

```
CRFESULT GetTimeSlices(ISHCTimeSliceEnumerator**
ppSHCTimeSliceEnumerator)
```

- `ppSHCTimeSliceEnumerator`
  [out]: The enumerator

"CreateTimeSlice" method

Adds an "ISHCTimeSlice" instance to the "ISHCShiftTemplate" instance.

```
CRFESULT CreateTimeSlice(ISHCTimeSlice* pSlice)
```

- `pSlice`
  [in]: Reference to the new time slice

"DeleteTimeSlice" method

Deletes an "ISHCTimeSlice" instance of the "ISHCShiftTemplate" instance.

```
CRFESULT DeleteTimeSlice(ISHCTimeSlice* pSlice)
```

- `pSlice`
  [in]: Reference to the time slice to be deleted

ISHCShiftTemplateEnumerator

Description

The C++ interface "ISHCShiftTemplateEnumerator" specifies methods for handling the enumeration of the shift templates of an "ISHCCalendar" instance. The enumeration is returned by the "Read" method of an "ISHCShiftTemplatesProvider" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(ISHCShiftTemplate** ppItem)
```

- `ppItem`
  [out]: The current shift template

"Reset" method

Reset the current position in the enumeration. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumeration or the number of its elements.

Supplies the number of shift templates in the list.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of shift templates

Example

Copy code

```
void PrintShiftTemplate(const ISHCShiftTemplateEnumeratorPtr& p_pShcShiftTemplateEnum)
{
   uint32_t nCout = 0;
   p_pShcShiftTemplateEnum->Count(&nCout);
   for (uint32_t nIndex = 0; nIndex < nCout; nIndex++)
   {
      cout << endl;
      p_pShcShiftTemplateEnum->MoveNext();
      ISHCShiftTemplatePtr pShcShiftTemplate;
      p_pShcShiftTemplateEnum->Current(&pShcShiftTemplate);
      CCfString strName;
      pShcShiftTemplate->GetName(&strName);
      std::cout << "Name=" << strName.ToUTF8().c_str() << std::endl;

      CCfTimeSpan64 tsDuration;
      pShcShiftTemplate->GetDuration(&tsdurantion);
      CCfString strDuration = tsdurantion.GetTimeSpanString();
      std::cout << "Duration=" << strDuration.ToUTF8().c_str() << std::endl;

      CFBOOL bIsDeleted;
      pShcShiftTemplate->GetIsDeleted(&bIsDeleted);
      std::cout << "ISDeleted=" << (uint32_t)bIsDeleted << std::endl;

      ICfMapIDToVariantPtr pDescriptions;
      pShcShiftTemplate->GetDescriptions(&pDescriptions);
      std::cout << "Descriptions=" << std::endl << std::endl;
      uint32_t nCount = 0;
      pDescriptions->Count(&nCount);
      for (uint32_t nIndex1 = 0; nIndex1 < nCount; nIndex1++)
      {
         int32_t nLanguageID;
         pDescriptions->KeyAt(nIndex1, &nLanguageID);
         CCfVariant strDescription;
         pDescriptions->ValueAt(nLanguageID, &strDescription);
         std::cout << "LangauageID =" << nLanguageID << " Description=" <<
CCfSmartString(strDescription).ToUTF8().c_str() << std::endl;
      }

      ICfMapIDToVariantPtr pDisplayNames;
      pShcShiftTemplate->GetDisplayNames(&pDisplayNames);
      std::cout << "DisplayNames::" << std::endl << std::endl;
      uint32_t nCount = 0;
      pDisplayNames->Count(&nCount);
      for (uint32_t nIndex1 = 0; nIndex1 < nCount; nIndex1++)
      {
         int32_t nLanguageID;
         pDisplayNames->KeyAt(nIndex1, &nLanguageID);
         CCfVariant strDIsplayname;
         pDisplayNames->ValueAt(nLanguageID, &strDIsplayname);
         std::cout << "LangauageID =" << nLanguageID << " DisplayName=" <<
CCfSmartString(strDIsplayname).ToUTF8().c_str() << std::endl;
      }
      ISHCTimeSliceEnumeratorPtr pShiftTemplatetimeSlice;
      pShcShiftTemplate->GetTimeSlices(&pShiftTemplatetimeSlice);
```

Copy code

```
        uint32_t nCout = 0;
        pShiftTemplatetimeSlice->Count(&nCout);
        for (uint32_t nIndex = 0; nIndex < nCout; nIndex++)
        {
           pShiftTemplatetimeSlice->MoveNext();
           cout << endl;
           ISHCTimeSlicePtr pTimeSlice;
           pShiftTemplatetimeSlice->Current(&pTimeSlice);
           CCfString strCategoryName;
           pTimeSlice->GetCategory(&strCategoryName);
           std::cout << "Category= " << strCategoryName.ToUTF8().c_str() << std::endl;

           CCfTimeSpan64 tsDuration;
           pTimeSlice->GetDuration(&tsDuration);
           CCfString strDuration = tsDuration.GetTimeSpanString();
           std::cout << "Durations= " << strDuration.ToUTF8().c_str() << std::endl;
           CCfDateTime64 dtStartTime;
           pTimeSlice->GetStartTime(&dtStartTime);
           CCfString strStarttime = dtStartTime.GetDateTimeString(false);
           std::cout << "Start Time= " << strStarttime.ToUTF8().c_str() << std::endl;
        }
     }
}
```

ISHCShiftTemplatesProvider

Description

The C++ interface "ISHCShiftTemplatesProvider" provides you with access to an "ISHCShiftTemplateEnumerator" instance which contains an enumeration with the shift templates of an "ISHCCalendar" instance. With the methods of the provider, you can create, read, update and delete shift templates. The provider is returned by the "GetShiftTemplateProvider" method of an "ISHCCalendar" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"Browse" method

Supplies an "ISHCShiftTemplateEnumerator" instance which has access to an enumeration with the "ISHCShiftTemplate" instances of the calendar.

```
CRFESULT Browse(CFBOOL includeDeleted,
ISHCShiftTemplateEnumerator** ppISHCShiftTemplateEnumerator)
```

- `includeDeleted`
  Saves whether the enumerator also has access to the deleted shift templates.
- `ppISHCShiftTemplateEnumerator`
  [out]: The enumerator

Example:

```
ISHCDayTemplateEnumeratorPtr pShcDayTemplates;
CFRESULT hr = pShcDayTemplateProvider->Browse(CF_FALSE,
&pShcDayTemplates);
```

"Create" method

Adds new shift templates to the enumeration with the "ISHCShiftTemplate" instances of the calendar.

```
CFRESULT Create(ICfArrayIUnknown* pShiftTemplates)
```

- `pShiftTemplates`
  [in]: An array with the shift templates to be added.

Example:

Copy code

```
void CreateShiftTemplateWithTimeslice()
{
   ISHCShiftTemplatePtr pShcShiftTemplate;
   ICfUnknownPtr pUnk;
   m_pCalendar->GetObject(ODK_SHC_SHIFT_TEMPLATE, &pUnk);
   pShcShiftTemplate = (ISHCShiftTemplatePtr)pUnk;
   pShcShiftTemplate->SetName(CCfString(L"ShiftTemplateName"));
   pShcShiftTemplate->SetDisplayName(1033, CCfString(L"ShiftDisplayName"));
   pShcShiftTemplate->SetDescription(1033, CCfString(L"ShiftTemplateDescription"));
   pShcShiftTemplate->SetDuration(Get1Hour() * 8);

   ICfArrayIUnknownPtr pArrayShiftTemplate;
   CCfArrayIUnknown ArrayShiftTemplate;
   ArrayShiftTemplate.Append(pShcShiftTemplate);
   ArrayShiftTemplate.DetachEnumerator(&pArrayShiftTemplate);
   m_pShcShiftTemplateProvider->Create(pArrayShiftTemplate);

   ICfUnknownPtr pUnkTimeSlice;
   m_pCalendar->GetObject(ODK_SHC_TIME_SLICE, &pUnkTimeSlice);
   ISHCTimeSlicePtr pShcTimeSlice;
   pUnkTimeSlice->QueryInterface(IID_ISHCTimeSlice, (ICfUnknown**)&pShcTimeSlice);
   pShcTimeSlice->SetCategory(CCfString(L"Working"));
   pShcTimeSlice->SetDuration(Get1Hour() * 1);
   CCfDateTime64 dt = GetStartoftheDay();
   pShcTimeSlice->SetStartTime(dt);
   pShcShiftTemplate->CreateTimeSlice(pShcTimeSlice);
}
```

"Update" method

Updates the enumeration with the "ISHCShiftTemplate" instances of the calendar.

```
CRFESULT Update(ICfArrayIUnknown* pShiftTemplates)
```

- `pShiftTemplates`
  [in]: An array with the shift templates to be updated.

Example:

Copy code

```
void UpdateShiftTemplateWithTimeSlice()
{
   ISHCShiftTemplateEnumeratorPtr pShcShiftTemplates;
   m_pShcShiftTemplateProvider->Browse(CF_FALSE, &pShcShiftTemplates);
   CCfArrayIUnknown ArrayShiftTemplate;
   ICfArrayIUnknownPtr pArrayShiftTemplate;
   uint32_t nCount = 0;
   pShcShiftTemplates->Count(&nCount);
   for (uint32_t i = 0; i < nCount; i++)
   {
      pShcShiftTemplates->MoveNext();
      ISHCShiftTemplatePtr pShcShiftTemplate;
      pShcShiftTemplates->Current(&pShcShiftTemplate);
      pShcShiftTemplate->SetDuration(Get1Hour() * 6);
      pShcShiftTemplate->SetName(CCfString(L"UpdatedShiftTemplateName"));

      ISHCTimeSliceEnumeratorPtr pTimeSlilceEnum;
      pShcShiftTemplate->GetTimeSlices(&pTimeSlilceEnum);
      uint32_t nlength = 0;
      pTimeSlilceEnum->Count(&nlength);
      for (uint32_t nIndex = 0; nIndex < nlenght; nIndex++)
      {
         pTimeSlilceEnum->MoveNext();
         ISHCTimeSlicePtr pShcTimeSlice;
         pTimeSlilceEnum->Current(&pShcTimeSlice);
         pShcTimeSlice->SetDuration(Get1Hour() * 4);
         pShcTimeSlice->SetCategory(CCfString(L"Break"));
      }
      ArrayShiftTemplate.Append(pShcShiftTemplate);
   }
   ArrayShiftTemplate.DetachEnumerator(&pArrayShiftTemplate);
   m_pShcShiftTemplateProvider->Update(pArrayShiftTemplate);
}
```

"Delete" method

Deletes an "ISHCShiftTemplate" instance of the calendar from the enumeration.

```
CRFESULT Delete(ICfArrayIUnknown* pShiftTemplates)
```

- `pShiftTemplates`
  [in]: An array with the shift templates to be deleted.

Example:

Copy code

```
void DeleteShiftTemplateWithTimeSlice()
{
   ISHCShiftTemplateEnumeratorPtr pShcShiftTemplates;
   m_pShcShiftTemplateProvider->Browse(CF_FALSE, &pShcShiftTemplates);
   CCfArrayIUnknown ArrayShiftTemplate;
   ICfArrayIUnknownPtr pArrayShiftTemplate;
   uint32_t nCount = 0;
   pShcShiftTemplates->Count(&nCount);
   for (uint32_t i = 0; i < nCount; i++)
   {
      pShcShiftTemplates->MoveNext();
      ISHCShiftTemplatePtr pShcShiftTemplate;
      pShcShiftTemplates->Current(&pShcShiftTemplate);
      ISHCTimeSliceEnumeratorPtr pTimeSlilceEnum;
      pShcShiftTemplate->GetTimeSlices(&pTimeSlilceEnum);
      uint32_t nlength = 0;
      pTimeSlilceEnum->Count(&nlength);
      for (uint32_t nIndex = 0; nIndex < nlenght; nIndex++)
      {
         pTimeSlilceEnum->MoveNext();
         ISHCTimeSlicePtr pShcTimeSlice;
         pTimeSlilceEnum->Current(&pShcTimeSlice);
         pShcShiftTemplate->DeleteTimeSlice(pShcTimeSlice);
      }
      ArrayShiftTemplate.Append(pShcShiftTemplate);
   }
   ArrayShiftTemplate.DetachEnumerator(&pArrayShiftTemplate);
   m_pShcShiftTemplateProvider->Delete(pArrayShiftTemplate);
}
```

ISHCShift

Description

The C++ interface "ISHCShift" specifies the methods of a shift.

The interface inherits from the "ICfUnknown" interface.

Members

"GetTimeSlices" method

Supplies an "ISHCTimeSliceEnumerator" instance. The enumerator provides you with access to the "ISHCTimeSlice" instances of the "ISHCShift" instance.

```
CRFESULT GetTimeSlices(ISHCTimeSliceEnumerator**
ppSHCTimeSliceEnumerator)
```

- `ppSHCTimeSliceEnumerator`
  [out]: The enumerator

"CreateTimeSlice" method

Adds an "ISHCTimeSlice" instance to the "ISHCShiftTemplate" instance.

```
CRFESULT CreateTimeSlice(ISHCTimeSlice* pSlice)
```

- `pSlice`
  [in]: Reference to the new time slice

Example

Copy code

```
void CreateTimeSliceUsingShift()
{
   ISHCDayTemplateEnumeratorPtr pShcDayTemplates;
   m_pShcDayTemplateProvider->Browse(CF_FALSE, &pShcDayTemplates);
   uint32_t nCount = 0;
   pShcDayTemplates->Count(&nCount);

   pShcDayTemplates->MoveNext();
   ISHCDayTemplatePtr pShcDayTemplate;
   pShcDayTemplates->Current(&pShcDayTemplate);
   ISHCShiftEnumeratorPtr pShiftEnum;
   pShcDayTemplate->GetShifts(&pShiftEnum);
   uint32_t nlength = 0;
   pShiftEnum->Count(&nlength);
   pShiftEnum->MoveNext();
   ISHCShiftPtr pShcShift;
   pShiftEnum->Current(&pShcShift);
   ISHCTimeSlicePtr pShcTimeSlice;
   ICfUnknownPtr pUnk;
   m_pCalendar->GetObject(ODK_SHC_TIME_SLICE, &pUnk);
   pShcTimeSlice = (ISHCTimeSlicePtr)pUnk;
   pShcTimeSlice->SetCategory(CCfString(L"Break"));
   pShcTimeSlice->SetDuration(Get1Hour() * 1);
   CCfDateTime64 dt = GetStartoftheDay();
   dt.AddTimeSpan(Get1Hour() * 3);
   pShcTimeSlice->SetStartTime(dt);

   pShcShift->CreateTimeSlice(pShcTimeSlice);
}
```

"DeleteTimeSlice" method

Deletes an "ISHCTimeSlice" instance of the "ISHCShiftTemplate" instance.

```
CRFESULT DeleteTimeSlice(ISHCTimeSlice* pSlice)
```

- `pSlice`
  [in]: Reference to the time slice to be deleted

Example:

Copy code

```
void DeleteTimeSliceUsingShift()
{
   ISHCDayTemplateEnumeratorPtr pShcDayTemplates;
   m_pShcDayTemplateProvider->Browse(CF_FALSE, &pShcDayTemplates);
   uint32_t nCount = 0;
   pShcDayTemplates->Count(&nCount);
   pShcDayTemplates->MoveNext();
   ISHCDayTemplatePtr pShcDayTemplate;
   ISHCShiftEnumeratorPtr pShiftEnum;
   pShcDayTemplate->GetShifts(&pShiftEnum);
   uint32_t nlength = 0;
   pShiftEnum->Count(&nlength);
   pShiftEnum->MoveNext();
   ISHCShiftPtr pShcShift;
   pShiftEnum->Current(&pShcShift);
   ISHCTimeSliceEnumeratorPtr pShcTimeSliceEnum;
   pShcShift->GetTimeSlices(&pShcTimeSliceEnum);
   uint32_t nCountTimeSlice = 0;
   pShcTimeSliceEnum->Count(&nCountTimeSlice);
   pShcTimeSliceEnum->MoveNext();
   ISHCTimeSlicePtr pShcTimeSlice;
   pShcTimeSliceEnum->Current(&pShcTimeSlice);
   pShcShift->DeleteTimeSlice(pShcTimeSlice);
}
```

"GetComments" method

Supplies a map with the comments of the "ISHCShift" instance and their language code IDs.

```
CRFESULT GetComments(ICfMapIDToVariant** ppComments)
```

- `ppComments`
  [out]: A map with int32/string pairs (language code ID for comment).

"SetComments" method

Adds a new entry to a map with the comments of the "ISHCShift" instance and their language code IDs.

```
CRFESULT SetComment(CFLCID languageId , CFSTR pComments)
```

- `languageId`
  [in]: The language code ID
- `pComments`
  [in]: The comment text

"GetDuration" method

Supplies the duration of the "ISHCShift" instance.

```
CFRESULT GetDuartion(CFTIMESPAN64* pDuration)
```

- `pDuration`
  [out]: The duration of the shift

"SetDuration" method

Sets the duration of the "ISHCShift" instance.

```
CFRESULT SetDuration(CFTIMESPAN64 duration)
```

- `duration`
  [in]: The duration of the shift

"GetShiftTemplate" method

Supplies the "ISHCShiftTemplate" instance on which the "ISHCShift" instance is based.

```
CRFESULT GetShiftTemplate(CFSTR* pSHCShiftTemplate)
```

- `pSHCShiftTemplate`
  [out]: The shift template

"CreateAction" method

Adds an "ISHCAction" instance to the "ISHCShift" instance.

```
CRFESULT CreateAction(ISHCActionTemplate* pActionTemplate,
CFTIMESPAN64 offset, ISHCAction** pShcAction)
```

- `pActionTemplate`
  [in]: The action template on which the new action is to be based.
- `offset`
  [in]: The offset of the action in relation to the start time of the "ISHCShift" instance. Positive and negative value allowed.
- `pShcAction`
  [out]: The new action

"DeleteAction" method

Deletes an "ISHCAction" instance of the "ISHCShift" instance.

```
CFRESULT DeleteAction(ISHCAction* pShcAction)
```

- `pShcAction`
  [in]: Reference to the action to be deleted.

"GetAction" method

Supplies an "ISHCActionEnumerator" instance via which you access the "ISHCAction" instances of the "ISHCShift" instance.

```
CRFESULT GetActions(ISHCActionEnumerator** ppSHCActionEnumerator)
```

- `ppSHCActionEnumerator`
  [out]: The enumerator

"GetIsCustomized" method

Supplies the information on whether the "ISHCShift" instance was edited by users.

```
CRFESULT GetIsCustomized)(CFBOOL* pIsCustomized)
```

- `pIsCustomized`
  [out]:
  - 0: Was not processed
  - 1: Was processed

"GetDeltaKind" method

Supplies the delta type of the "ISHCShift" instance.

```
CRFESULT GetDeltaKind(CFENUM* pDeltaKind)
```

- `pDeltaKind`
  [out]: Points to the enumeration "ShcDeltaType", which can contain the following values:
  - Added (0)
  - Modified (1)
  - Deleted (2)

"GetShiftId" method

Supplies the ID of the "ISHCShift" instance.

```
CFRESULT GetShiftId(uint32_t* pShiftId)
```

- `pShift`
  [out]: The ID

"SetShiftId" method

Sets the ID of the "ISHCShift" instance.

```
SetShiftId(uint32_t ShiftId)
```

- `ShiftId`
  [in]: The new ID

ISHCShiftEnumerator

Description

The C++ interface "ISHCShiftEnumerator" specifies methods for handling the enumeration of shifts of an "ISHCDay" instance or "ISHCDayTemplate" instance.

The enumeration is returned by the "GetShifts" method of these instances.

The interface inherits from the "ICfUnknown" interface.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(ISHCShift** ppItem)
```

- `ppItem`
  [out]: The current shift

"Reset" method

Reset the current position in the enumeration. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumeration or the number of its elements.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of shifts

Example

Copy code

```
void printShift(const ISHCShiftEnumeratorPtr& p_pShcShiftEnum)
{
   uint32_t nCout = 0;
   p_pShcShiftEnum->Count(&nCout);
   for (uint32_t nIndex = 0; nIndex < nCout; nIndex++)
   {
      cout << endl;
      p_pShcShiftEnum->MoveNext();
      ISHCShiftPtr pShcshift;
      p_pShcShiftEnum->Current(&pShcshift);
      CCfString strshiftTemplateName;
      pShcshift->GetShiftTemplate(&strshiftTemplateName);
      std::cout << "ShiftTemplateName= " << strshiftTemplateName.ToUTF8().c_str() <<
std::endl;
      CCfTimeSpan64 tsDuration;
      pShcshift->GetDuration(&tsDuration);
      CCfString strDuration = tsDuration.GetTimeSpanString();
      std::cout << "Durations= " << strDuration.ToUTF8().c_str() << std::endl;
      CFBOOL bIsCustomised;
      pShcshift->GetIsCustomized(&bIsCustomised);
      std::cout << "Is Customised= " << (uint32_t)bIsCustomised << std::endl;
      CFENUM ndeltaKind;
      pShcshift->GetDeltaKind(&ndeltaKind);
      std::cout << "deltaKind = " << ndeltaKind << std::endl;
      uint32_t nShiftId;
      pShcshift->GetShiftId(&nShiftId);
      std::cout << "ShiftId = " << nShiftId << std::endl;
      ICfMapIDToVariantPtr pComments;
      pShcshift->GetComments(&pComments);
      std::cout << "comments:-" << std::endl << std::endl;
      uint32_t nCount = 0;
      pComments->Count(&nCount);
      for (uint32_t nIndex1 = 0; nIndex1 < nCount; nIndex1++)
      {
         int32_t nLanguageID;
         pComments->KeyAt(nIndex1, &nLanguageID);
         CCfVariant strComments;
         pComments->ValueAt(nLanguageID, &strComments);
         std::cout << "LangauageID =" << nLanguageID << " Comments=" <<
CCfSmartString(strComments).ToUTF8().c_str() << std::endl;
      }
      ISHCTimeSliceEnumeratorPtr pShiftTimesliceEnum;
      pShcshift->GetTimeSlices(&pShiftTimesliceEnum);

      uint32_t nCout = 0;
      pShiftTimesliceEnum->Count(&nCout);
      for (uint32_t nIndex = 0; nIndex < nCout; nIndex++)
      {
         pShiftTimesliceEnum->MoveNext();
         cout << endl;
         ISHCTimeSlicePtr pTimeSlice;
         pShiftTimesliceEnum->Current(&pTimeSlice);
         CCfString strCategoryName;
         pTimeSlice->GetCategory(&strCategoryName);
```

Copy code

```
            std::cout << "Category= " << strCategoryName.ToUTF8().c_str() << std::endl;

            CCfTimeSpan64 tsDuration;
            pTimeSlice->GetDuration(&tsDuration);
            CCfString strDuration = tsDuration.GetTimeSpanString();
            std::cout << "Durations= " << strDuration.ToUTF8().c_str() << std::endl;
            CCfDateTime64 dtStartTime;
            pTimeSlice->GetStartTime(&dtStartTime);
            CCfString strStarttime = dtStartTime.GetDateTimeString(false);
            std::cout << "Start Time= " << strStarttime.ToUTF8().c_str() << std::endl;
        }
    }
}
```

ISHCAction

Description

The C++ interface "ISHCAction" specifies the methods of an action.

The interface inherits from the "ICfUnknown" interface.

Members

"GetOffset" method

Returns the offset of the "ISHCAction" instance in relation to the starting point of its "ISHCShift" instance.

```
CFRESULT GetOffset(CFTIMESPAN64* pOffsetType)
```

- `pOffset`
  [out]: The offset in 100 nanoseconds. Positive and negative value allowed.

"SetOffset" method

Sets the offset of the "ISHCAction" instance in relation to the starting point of its "ISHCShift" instance.

```
CFRESULT GetOffset(CFTIMESPAN64 OffsetType)
```

- `OffsetType`
  [in]: The offset in 100 nanoseconds. Positive and negative value allowed.

"GetActionTemplate" method

Supplies the "ISHCActionTemplate" instance of the "ISHCAction" instance.

```
GetActionTemplate(CFSTR* p_strActionTemplate)
```

- `p_strActionTemplate`
  [out]: The action template

"GetIsCustomized" method

Supplies the information on whether the "ISHCAction" instance was edited by users.

```
CRFESULT GetIsCustomized(CFBOOL* pIsCustomized)
```

- `pIsCustomized`
  [out]:
  - 0: Was not processed
  - 1: Was processed

"GetElements" method

Supplies an "ISHCActionElementEnumerator" instance via which you access the action elements of the "ISHCAction" instance.

```
GetElements(ISHCActionElementEnumerator**
ppSHCActionElementEnumerator)
```

- `ppSHCActionElementEnumerator`
  [out]: The enumerator

ISHCActionEnumerator

Description

The C++ interface "ISHCActionEnumerator" specifies methods for handling the enumeration of actions of an "ISHCShift" instance or "ISHCShiftTemplate" instance.

The enumeration is returned by the "GetActions" method of these instances.

The interface inherits from the "IcfUnknown" interface.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(ISHCAction** ppItem)
```

- `ppItem`
  [out]: The current action

"Reset" method

Reset the current position in the enumeration. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumeration or the number of its elements.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of actions

Example

Copy code

```
void PrintAction(const ISHCActionEnumeratorPtr& pShcActionEnum)
{
   uint32_t nCount = 0;
   pShcActionEnum->Count(&nCount);
   for (uint32_t nIndex = 0; nIndex < nCount; nIndex++)
   {
      cout << endl;
      pShcActionEnum->MoveNext();
      ISHCActionPtr pShcAction;
      pShcActionEnum->Current(&pShcAction);
      CCfString strActionTemplateName;
      pShcAction->GetActionTemplate(&strActionTemplateName);
      std::cout << "ActionTemplateName = " << strActionTemplateName.ToUTF8().c_str() <<
std::endl;
      CFBOOL isCustomize;
      pShcAction->GetIsCustomized(&isCustomize);
      cout << "IsCustomize= " << (uint32_t)isCustomize << endl;

      CCfTimeSpan64 offset;
      hr = pShcAction->GetOffset(&offset);
      cout << "Offset=" << offset.GetTimeSpanString().ToUTF8().c_str() << endl;
      ISHCActionElementEnumeratorPtr pShcActionElementEnum;
      pShcAction->GetElements(&pShcActionElementEnum);

      cout << endl << "******PrintActionElement*******" << endl << endl;
      uint32_t nCount = 0;
      pShcActionElementEnum->Count(&nCount);
      for (uint32_t nIndex = 0; nIndex < nCount; nIndex++)
      {
         cout << endl;
         pShcActionElementEnum->MoveNext();
         ISHCActionElementPtr pShcActionElement;
         pShcActionElementEnum->Current(&pShcActionElement);
         CCfString strElementName;
         pShcActionElement->GetElementName(&strElementName);
         cout << "ActionElementName= " << strElementName.ToUTF8().c_str() << endl;
         CFENUM nType;
         pShcActionElement->GetElementType(&nType);
         cout << "Element Type= " << nType << endl;
         CFBOOL bIsEnable;
         pShcActionElement->GetEnabled(&bIsEnable);
         cout << "Is Enable = " << (uint32_t)bIsEnable << endl;
         CCfTimeSpan64 offset;
         pShcActionElement->GetOffset(&offset);
         cout << "Offset = " << offset.GetTimeSpanString().ToUTF8().c_str() << endl;
         CCfVariant vtValue;
         pShcActionElement->GetValue(&vtValue);
         cout << "value = " << vtValue.uint32 << endl;
      }
   }
}
```

ISHCActionElement

Description

The C++ interface "ISHCActionElement" specifies the methods of the action elements of an "ISHCAction" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"GetElementType" method

Supplies the type of the "ISHCActionElement" instance.

```
CRFESULT GetElementType(CFENUM* pElementType)
```

- `pElementType`
  [out]: Points to the enumeration "ShcActionElementType", which can contain the following values:
  - `Tag` (0)
    The action element controls a tag.

"GetEnabled" method

Supplies the information on whether the "ISHCActionElement" instance is activated.

```
CRFESULT GetEnabled(CFBOOL* pEnabled)
```

- `pEnabled`
  [out]:
  - 0: Deactivated
  - 1: Activated

"SetEnabled" method

Sets whether the "ISHCActionElement" instance is activated.

```
CRFESULT SetEnabled(CFBOOL Enabled)
```

- `Enabled`
  [in]:
  - 0: Deactivated
  - 1: Activated

"GetOffset" method

Returns the offset of the "ISHCActionElement" instance in relation to the anchor point of its "ISHCAction" instance.

```
CFRESULT GetOffset(CFTIMESPAN64* pOffset)
```

- `pOffset`
  [out]: The offset in 100 nanoseconds. Positive and negative value allowed.

"SetOffset" method

Sets the offset of the "ISHCActionElement" instance in relation to the anchor point of its "ISHCAction" instance.

```
CFRESULT SetOffset(CFTIMESPAN64 offset)
```

- `offset`
  [in]: The offset in 100 nanoseconds. Positive and negative value allowed.

"GetValue" method

Supplies the value of the tag controlled by the "ISHCActionElement" instance.

```
CFRESULT GetValue(CFVARIANT* pValue)
```

- `pValue`
  [out]: The tag value

"SetValue" method

Sets the value of the tag controlled by the "ISHCActionElement" instance.

```
CRFESULT SetValue(CFVARIANT value)
```

- `value`
  [in]: The new tag value

"GetElementName" method

Supplies the name of the tag controlled by the "ISHCActionElement" instance.

```
CFRESULT GetElementName(CFSTR* p_strActionElement)
```

- `p_strActionElement`
  [out]: The tag name

"SetElementName" method

Sets the name of the tag controlled by the "ISHCActionElement" instance.

```
CFRESULT SetElementName(CFSTR ActionElement)
```

- `ActionElement`
  [in]: The tag name

ISHCActionElementEnumerator

Description

The C++ interface "ISHCActionElementEnumerator" specifies methods for handling the enumeration of action elements of an "ISHCAction" instance.

The enumeration is returned by the "GetElements" method of an "ISHCAction" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(ISHCActionElement** ppItem)
```

- `ppItem`
  [out]: The current action element

"Reset" method

Reset the current position in enumeration. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumeration or the number of elements.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of action elements

Example

Copy code

```
 void PrintActionElement(const ISHCActionElementEnumeratorPtr& pShcActionElementEnum)
{
      cout << endl << "******PrintActionElement*******" << endl << endl;
      uint32_t nCount = 0;
      pShcActionElementEnum->Count(&nCount);
      for (uint32_t nIndex = 0; nIndex < nCount; nIndex++)
      {
         cout << endl;
         pShcActionElementEnum->MoveNext();
         ISHCActionElementPtr pShcActionElement;
         pShcActionElementEnum->Current(&pShcActionElement);
         CCfString strElementName;
         pShcActionElement->GetElementName(&strElementName);
         cout << "ActionElementName= " << strElementName.ToUTF8().c_str() << endl;
         CFENUM nType;
         pShcActionElement->GetElementType(&nType);
         cout << "Element Type= " << nType << endl;
         CFBOOL bIsEnable;
         pShcActionElement->GetEnabled(&bIsEnable);
         cout << "Is Enable = " << (uint32_t)bIsEnable << endl;
         CCfTimeSpan64 offset;
         pShcActionElement->GetOffset(&offset);
         cout << "Offset = " << offset.GetTimeSpanString().ToUTF8().c_str() << endl;
         CCfVariant vtValue;
         pShcActionElement->GetValue(&vtValue);
         cout << "value = " << vtValue.uint32 << endl;
      }
}
```

ISHCActionTemplate

Description

The C++ interface "ISHCActionTemplate" specifies the methods of an action template.

The interface inherits from the "ICfUnknown" interface.

Members

"GetName" method

Supplies the name of the "ISHCActionTemplate" instance.

```
CFRESULT GetName(CFSTR * pvarRet)
```

- `pvarRet`
  [out]: The name of the action template

"SetName" method

Sets the name of the "ISHCActionTemplate" instance

```
CFRESULT SetName(CFSTR  value)
```

- `value`
  [in]: The name

"GetDisplayNames" method

Supplies a map with the display names of the "ISHCActionTemplate" instance and their language code IDs.

```
CFRESULT GetDisplayNames)(ICfMapIDToVariant** ppDisplayNames)
```

- `ppDisplayNames`
  [out]: The map with String/String pairs (language code ID for display name).

"SetDisplayNames" method

Adds a display name and its language code ID to the map with the display name of the "ISHCActionTemplate" instance.

```
CFRESULT SetDisplayNames)(CFLCID languageId, CFSTR pDisplayName)
```

- `languageID`
  [in]: The language code ID of the display name
- `pDisplayName`
  [in]: The display name

"GetDescriptions" method

Supplies a map with the descriptions of the "ISHCActionTemplate" instance and their language code IDs.

```
CFRESULT GetDescriptions(ICfMapIDToVariant** value)
```

- `value`
  [out]: The map with String/String pairs (language code ID for description).

"SetDescriptions" method

Adds a description and its language code ID to the map with the descriptions of the "ISHCActionTemplate" instance.

```
CFRESULT SetDescription(CFLCID languageId, CFSTR pDescriptions)
```

- `languageID`
  [in]: The language code ID of the description
- `pDescriptions`
  [in]: The description text

"GetIsDeleted" method

Supplies the information on whether the "ISHCActionTemplate" instance was deleted by users.

```
CFRESULT GetIsDeleted(CFBOOL* pIsDeleted)
```

- `pIsDeleted`
  [out]:
  - 0: Was not deleted
  - 1: Was deleted

"GetElements" method

Supplies an "ISHCActionTemplateElementEnumerator" instance. The enumerator provides you with access to the "ISHCActionTemplateElement" instances of the "ISHCActionTemplate" instance.

```
CRFESULT GetElements(ISHCActionTemplateElementEnumerator**
ppISHCActionTemplateElementEnumerator)
```

- `ppISHCActionTemplateElementEnumerator`
  [out]: The enumerator

"CreateElement" method

Adds an "ISHCActionTemplateElement" instance to the "ISHCActionTemplate" instance.

```
CRFESULT CreateElement(ISHCActionTemplateElement*
pSHCActionTemplateElement)
```

- `pSHCActionTemplateElement`
  [in]: Reference to the new action element

"DeleteElement" method

Deletes an action element of the "ISHCActionTemplate" instance.

```
CRFESULT DeleteElement(ISHCActionTemplateElement*
pSHCActionTemplateElement)
```

- `pSHCActionTemplateElement`
  [in]: Reference to the action element to be deleted

ISHCActionTemplateEnumerator

Description

The C++ interface "ISHCActionTemplateEnumerator" specifies methods for handling the enumeration of the action templates of an "ISHCCalendar" instance.

The enumeration is returned by the "Read" method of an "ISHCActionTemplatesProvider" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(ISHCActionTemplate** ppItem)
```

- `ppItem`
  [out]: The current action template

"Reset" method

Reset the current position in the enumeration. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumeration or the number of elements.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of action templates

Example

Copy code

```
void PrintActionTemplate(const ISHCActionTemplateEnumeratorPtr& p_pShcActionTemplateEnum)
{
   uint32_t nCount = 0;
   p_pShcActionTemplateEnum->Count(&nCount);
   for (uint32_t nIndex = 0; nIndex < nCount; nIndex++)
   {
      cout << endl;
      p_pShcActionTemplateEnum->MoveNext();
      ISHCActionTemplatePtr pShcActionTemplate;
      p_pShcActionTemplateEnum->Current(&pShcActionTemplate);
      CCfString strActionTemplateName;
      pShcActionTemplate->GetName(&strActionTemplateName);
      cout << "ActionTemplateName=" << strActionTemplateName.ToUTF8().c_str() << endl;

      CFBOOL bIsDeleted;
      pShcActionTemplate->GetIsDeleted(&bIsDeleted);
      cout << "IsDeleted=" << (uint32_t)bIsDeleted << endl;
      ICfMapIDToVariantPtr pDescriptions;
      pShcActionTemplate->GetDescriptions(&pDescriptions);
      std::cout << "Descriptions=" << std::endl << std::endl;
      uint32_t nCount1 = 0;
      pDescriptions->Count(&nCount1);
      for (uint32_t nIndex1 = 0; nIndex1 < nCount1; nIndex1++)
      {
         int32_t nLanguageID;
         pDescriptions->KeyAt(nIndex1, &nLanguageID);
         CCfVariant strDescription;
         pDescriptions->ValueAt(nLanguageID, &strDescription);
         std::cout << "LangauageID =" << nLanguageID << " Description=" <<
CCfSmartString(strDescription).ToUTF8().c_str() << std::endl;
      }

      ICfMapIDToVariantPtr pDisplayNames;
      pShcActionTemplate->GetDisplayNames(&pDisplayNames);
      std::cout << "DisplayNames::" << std::endl << std::endl;
      uint32_t nCount1 = 0;
      pDisplayNames->Count(&nCount1);
      for (uint32_t nIndex1 = 0; nIndex1 < nCount1; nIndex1++)
      {
         int32_t nLanguageID;
         pDisplayNames->KeyAt(nIndex1, &nLanguageID);
         CCfVariant strDIsplayname;
         pDisplayNames->ValueAt(nLanguageID, &strDIsplayname);
         std::cout << "LangauageID =" << nLanguageID << " DisplayName=" <<
CCfSmartString(strDIsplayname).ToUTF8().c_str() << std::endl;
      }

      ISHCActionTemplateElementEnumeratorPtr pShcActionTemplateElementEnum;
      pShcActionTemplate->GetElements(&pShcActionTemplateElementEnum);

      uint32_t nCount2 = 0;
      pShcActionTemplateElementEnum   ->Count(&nCount2);
      for (uint32_t nIndex = 0; nIndex < nCount2; nIndex++)

```

Copy code

```
          pShcActionTemplateElementEnum   ->MoveNext();
          ISHCActionTemplateElementPtr pShcActionTemplateElement;
          pShcActionTemplateElementEnum   ->Current(&pShcActionTemplateElement);
          CCfString strElementName;
          pShcActionTemplateElement->GetElementName(&strElementName);
          cout << "TemplateElementName= " << strElementName.ToUTF8().c_str() << endl;
          CFENUM type;
          pShcActionTemplateElement->GetElementType(&Type);
          cout << "ElementType=" << Type << endl;
          CCfTimeSpan64 tsOffset;
         cout << "Element Offset=" << tsOffset.GetTimeSpanString().ToUTF8().c_str() << endl;
          CCfVariant vtValue;
          pShcActionTemplateElement->GetValue(&vtValue);
          cout << "Value=" << vtValue.uint32 << endl;
       }
    }
}
```

ISHCActionTemplatesProvider

Description

The C++ interface "ISHCActionTemplatesProvider" provides you with access to an "ISHCActionTemplateEnumerator" instance which contains an enumeration with the action templates of an "ISHCCalendar" instance. With the methods of the provider, you can create, read, update and delete action templates. The provider is returned by the "GetActionTemplatesProvider" method of an "ISHCCalendar" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"Browse" method

Supplies an "ISHCActionTemplateEnumerator" instance which has access to an enumeration with the "ISHCActionTemplate" instances of the calendar.

```
CRFESULT Browse(CFBOOL includeDeleted,OUT
ISHCActionTemplateEnumerator** ppISHCActionTemplateEnumerator)
```

- `includeDeleted`
  Saves whether the enumerator also has access to the deleted action templates.
- `ppISHCActionTemplateEnumerator`
  [out]: The enumerator

Example:

```
ISHCActionTemplateEnumeratorPtr pShcActionTemplateEnum;
pShcActionTemplateProvider->Browse(CF_FALSE,
&pShcActionTemplateEnum);
```

"Create" method

Adds new action templates to the enumeration with the "ISHCActionTemplate" instances of the calendar.

```
CFRESULT Create(ICfArrayIUnknown* pActionTemplates)
```

- `pActionTemplates`
  [in]: An array with the action templates to be added.

Example:

Copy code

```
void CreateActionTemplateWithActionTemplateElement()
{
   ICfUnknownPtr pUnk;
   m_pCalendar->GetObject(ODK_SHC_ACTION_TEMPLATE, &pUnk);
   CCfArrayIUnknown ArrayTemplate;
   ICfArrayIUnknownPtr pArrayTemplate;
   ISHCActionTemplatePtr pShcActionTemplate = (ISHCActionTemplatePtr)pUnk;
   pShcActionTemplate->SetName(CCfString(L"ActionTemplateName"));
   pShcActionTemplate->SetDisplayName(1033, CCfString(L"ActionTemplateDisplayName"));
   pShcActionTemplate->SetDescription(1033, CCfString(L"ActionTemplateDescription"));
   ArrayTemplate.Append(pShcActionTemplate);
   ArrayTemplate.DetachEnumerator(&pArrayTemplate);
   m_pShcActionTemplateProvider->Create(pArrayTemplate);
   m_pCalendar->GetObject(ODK_SHC_ACTION_TEMPLATE_ELEMENT, &pUnk);
   ISHCActionTemplateElementPtr pShcActionTemplateElement =
(ISHCActionTemplateElementPtr)pUnk;
   pShcActionTemplateElement->SetElementName(CCfString(L"HMI_RT_1::Unit1.Member_1"));
   CFTIMESPAN64 Offset = Get1Hour();
   pShcActionTemplateElement->SetOffset(Offset);
   uint32_t value = 1;
   pShcActionTemplateElement->SetValue(CCfVariant(value));
   pShcActionTemplate->CreateElement(pShcActionTemplateElement);
}
```

"Update" method

Updates "ISHCActionTemplate" instances of the enumeration.

```
CRFESULTUpdate(ICfArrayIUnknown* pActionTemplates)
```

- `pActionTemplates`
  [in]: An array with the action templates to be updated.

Example:

Copy code

```
void UpdateActionTemplateWithActionTemplateElement()
{
   ISHCActionTemplateEnumeratorPtr pShcActionTemplateEnum;
   m_pShcActionTemplateProvider->Browse(CF_FALSE, &pShcActionTemplateEnum);
   pShcActionTemplateEnum->MoveNext();
   CCfArrayIUnknown ArrayActionTemplate;
   ICfArrayIUnknownPtr pArrayActionTemplate;
   ISHCActionTemplatePtr pShcActionTemplate;
   pShcActionTemplateEnum->Current(&pShcActionTemplate);
   pShcActionTemplate->SetName(CCfString(L"UpdatedActionTemplate"));
   pShcActionTemplate->SetDisplayName(1033,
CCfString(L"UpdatedActionTemplateDisplayName"));
   ISHCActionTemplateElementEnumeratorPtr pShcActionTemplateElementEnum;
   pShcActionTemplate->GetElements(&pShcActionTemplateElementEnum);
   pShcActionTemplateElementEnum->MoveNext();
   ISHCActionTemplateElementPtr pShcActionTemplateElement;
   pShcActionTemplateElementEnum->Current(&pShcActionTemplateElement);
   CCfTimeSpan64 offset = Get1Hour() * 2;
   pShcActionTemplateElement->SetOffset(offset);
   uint32_t nValue = 2;
   pShcActionTemplateElement->SetValue(CCfVariant(nValue));

   ArrayActionTemplate.Append(pShcActionTemplate);
   ArrayActionTemplate.DetachEnumerator(&pArrayActionTemplate);
   m_pShcActionTemplateProvider->Update(pArrayActionTemplate);
}
```

"Delete" method

Deletes "ISHCActionTemplate" instances of the calendar from the enumeration.

```
CRFESULT Delete(ICfArrayIUnknown* pActionTemplates)
```

- `pActionTemplates`
  [in]: An array with the action templates to be deleted.

Example:

Copy code

```
void DeleteActionTemplateWithActionTemplateElement()
{
   CFRESULT hr = CF_ERROR;
   ISHCActionTemplateEnumeratorPtr pShcActionTemplateEnum;
   m_pShcActionTemplateProvider->Browse(CF_FALSE, &pShcActionTemplateEnum);
   pShcActionTemplateEnum->MoveNext();
   CCfArrayIUnknown ArrayActionTemplate;
   ICfArrayIUnknownPtr pArrayActionTemplate;
   ISHCActionTemplatePtr pShcActionTemplate;
   pShcActionTemplateEnum->Current(&pShcActionTemplate);
   ISHCActionTemplateElementEnumeratorPtr pShcActionTemplateElementEnum;
   pShcActionTemplate->GetElements(&pShcActionTemplateElementEnum);
   pShcActionTemplateElementEnum->MoveNext();
   ISHCActionTemplateElementPtr pShcActionTemplateElement;
   pShcActionTemplateElementEnum->Current(&pShcActionTemplateElement);
   pShcActionTemplate->DeleteElement(pShcActionTemplateElement);

   ArrayActionTemplate.Append(pShcActionTemplate);
   ArrayActionTemplate.DetachEnumerator(&pArrayActionTemplate);
   m_pShcActionTemplateProvider->Delete(pArrayActionTemplate);
}
```

ISHCActionTemplateElement

Description

The C++ interface "ISHCActionTemplateElement" specifies the methods of an action template.

The interface inherits from the "ICfUnknown" interface.

Members

"GetElementType" method

Supplies the type of the "ISHCActionTemplateElement" instance.

`CRFESULT GetElementType(CFENUM* pElementType)`

- `pElementType`
  [out]: Points to the enumeration "ShcActionElementType", which can contain the following values:
  - `Tag` (0)
    The action element controls a tag.

"GetOffset" method

Returns the offset of the "ISHCActionTemplateElement" instance in relation to the anchor point of its "ISHCActionTemplate" instance.

```
CFRESULT GetOffset(CFTIMESPAN64* pOffset)
```

- `pOffset`
  [out]: The offset in 100 nanoseconds. Positive and negative value allowed.

"SetOffset" method

Sets the offset of the "ISHCActionTemplateElement" instance in relation to the anchor point of its "ISHCActionTemplate" instance.

```
CFRESULT SetOffset(CFTIMESPAN64 offset)
```

- `offset`
  [in]: The offset in 100 nanoseconds. Positive and negative value allowed.

"GetElementName" method

Supplies the name of the tag controlled by the "ISHCActionTemplateElement" instance.

```
CFRESULT GetElementName(CFSTR* pElementName)
```

- `pElementName`
  [out]: The tag name

"SetElementName" method

Sets the name of the tag controlled by the "ISHCActionTemplateElement" instance.

```
CFRESULT SetElementName(CFSTR pElementName)
```

- `pElementName`
  [in]: The tag name

"GetValue" method

Supplies the value of the tag controlled by the "ISHCActionTemplateElement" instance.

```
CFRESULT GetValue(CFVARIANT* pValue)
```

- `pValue`
  [out]: The tag value

"SetValue" method

Sets the value of the tag controlled by the "ISHCActionTemplateElement" instance.

```
CRFESULT SetValue(CFVARIANT pValue)
```

- `pValue`
  [in]: The new tag value

ISHCActionTemplateElementEnumerator

Description

The C++ interface "ISHCActionTemplateElementEnumerator" specifies methods for handling the enumeration of "ISHCActionTemplateElement" instances of an "ISHCActionTemplate" instance.

The enumeration is returned by the "GetElements" method of an "ISHCActionTemplate" instance.

The interface inherits from the "ICfUnknown" interface.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(ISHCActionTemplateElement** ppItem)
```

- `ppItem`
  [out]: The current action element of the action template

"Reset" method

Reset the current position in the enumeration. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumeration or the number of elements.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of "ISHCActionTemplateElement" instances

Example

Copy code

```
void PrintActionTemplateElement(const ISHCActionTemplateElementEnumeratorPtr&
pShcActionTemplateElementEnum   )
{
   uint32_t nCount = 0;
   pShcActionTemplateElementEnum   ->Count(&nCount);
   for (uint32_t nIndex = 0; nIndex < nCount; nIndex++)
   {
      pShcActionTemplateElementEnum   ->MoveNext();
      ISHCActionTemplateElementPtr pShcActionTemplateElement;
      pShcActionTemplateElementEnum   ->Current(&pShcActionTemplateElement);
      CCfString strElementName;
      pShcActionTemplateElement->GetElementName(&strElementName);
      cout << "TemplateElementName= " << strElementName.ToUTF8().c_str() << endl;
      CFENUM type;
      pShcActionTemplateElement->GetElementType(&Type);
      cout << "ElementType=" << Type << endl;
      CCfTimeSpan64 tsOffset;
      cout << "Element Offset=" << tsOffset.GetTimeSpanString().ToUTF8().c_str() << endl;
      CCfVariant vtValue;
      pShcActionTemplateElement->GetValue(&vtValue);
      cout << "Value=" << vtValue.uint32 << endl;
   }
}
```

20.3.9.8 Interfaces of the contexts

IContextLogging

Description

The C++ interface "IContextLogging" defines events and methods for creating and reading "IContextDefinition" instances as well as for starting, stopping, monitoring and reading their "ILoggedContext" instances. You can use "ILoggedContext" instances to filter runtime data, for example, for alarms that fall within the time period of a particular "ILoggedContext" instance.

The interface implements the methods of the "ICfUnknown" interface.

All methods return CF_SUCCESS after successful execution. In the case of an error, the methods return the corresponding error code.

Members

"CreateContextDefinitions" method

Creates ContextDefinitions in the database.

```
CRFESULT CreateContextDefintions(ICfArrayIUnknown*
pContextDefinitions, IContextLoggingCallBack *pContextCallBack)
```

- `pContextDefinitions`:
  [in]: Collection with "IContextDefinition" instances
- `*pContextCallBack`:
  [in]: Points to the "IContextLoggingCallBack" object that implements the callback interface.

"ReadContextDefinitions" method

Reads ContextDefinitions from the database. The instances can be filtered by plant object and HMIContextProviderType .

```
CRFESULT ReadContextDefinitions(IContextLoggingCallBack*
pContextCallBack, ICfArrayString* plantViewPaths, ICfArrayVariant*
pProviderTypes, CFENUM sortingMode)
```

- `pContextCallBack`:
  [in]: Points to the "IContextLoggingCallBack" object that implements the callback interface.
- `plantViewPaths`:
  [in]: Limits the read operation to "IContextDefinition" instances from this collection of plant objects.
- `pProviderTypes`:
  [in/optional]: Limits the read operation to "IContextDefinition" instances with HmiContextProvider types from this collection.
  The enumeration "HmiContextProviderType" can contain the following values:
  - NoContext = 0
  - Calendar = 1
    For "IContextDefinition" instances generated by the PI Option Calendar.
  - PerformanceInsightMachineState = 2
    For "IContextDefinition" instances generated by the PI Option Performance Insight.
  - LineCoordinator = 3
    For "IContextDefinition" instances generated by the PI Option Line Coordinator.
  - UserDefined = 5
    It is a user-defined "IContextDefinition" instance, created by ODK, for example.
- `sortingMode`:
  [in]: Points to the enumeration HmiContextLoggingSortingMode, which can contain the following values:
  - Ascending = 1
    Default setting
  - Descending = 2

"ReadContexts" method

Reads "ILoggedContext" instances of a specific time period. The instances can be filtered using a "IContextFilter" instance.

```
CRFESULT ReadContexts(CFDATETIME64 start, CFDATETIME64
end, IContextLoggingCallBack* ContextCallBack, IContextFilter*
FilterObject, CFENUM type)
```

- `start`:
  [in]: The start time of the period within which the "ILoggedContext" instances must lie.
- `end`:
  [in]: The end time of the period within which the "ILoggedContext" instances must lie.
- `ContextCallBack`:
  [in]: Points to the "IContextLoggingCallBack" object that implements the callback interface.
- `FilterObject`:
  [in/optional]: The "IContextFilter" instance whose filter settings are used.
- `type`:
  [in]: Points to the enumeration HmiContextLoggingSortingMode, which can contain the following values:
  - Ascending = 1
    Default setting
  - Descending = 2

"StartContext" method

Creates a new "ILoggedContext" instance for a "IContextDefinition" instance.

```
CRFESULT StartContext(CFSTR p_strContextName, CFENUM providerType,
CFSTR plantViewPath, CFVARIANT contextValue, CFDATETIME64
startTime, uint32_t qualityCode)
```

- `p_strContextName`:
  [in]: The name of the "IContextDefinition" instance for which the context log entry is created.
- `providerType`:
  [in]: The HmiContextProviderType that the "IContextDefinition" instance of the context log entry must have.
  The enumeration "HmiContextProviderType" can contain the following values:
  - NoContext = 0
  - Calendar = 1
    For "IContextDefinition" instances generated by the PI Option Calendar.
  - PerformanceInsightMachineState = 2
    For "IContextDefinition" instances generated by the PI Option Performance Insight.
  - LineCoordinator = 3
    For "IContextDefinition" instances generated by the PI Option Line Coordinator.
  - UserDefined = 5
    It is a user-defined "IContextDefinition" instance, created by ODK, for example.
- `plantViewPath`:
  [in]: Path to an "IPlantObject" instance
  E.g.: ".hierarchy::PlantView/Ln_1/M_1"
  Is used in combination with `p_strContextName` for unique identification of the "IContextDefinition" instance.

- `contextValue`:
  [in]: The context value of the context log entry
- `startTime`:
  [in]: Start time of the new context log entry
- `qualityCode`:
  [in]: The QualityCode of the context value of the context log entry

"StopContext" method

Stops the currently running "ILoggedContext" instance of an "IContextDefinition" instance.

```
CRFESULT StopContext(CFSTR p_strContextName, CFENUM providerType,
CFSTR plantViewPath, CFDATETIME64 endtime)
```

- `p_strContextName`:
  [in]: The name of the "IContextDefinition" instance whose context log entry is stopped.
- `providerType`:
  [in]: The HmiContextProviderType that the "IContextDefinition" instance of the context log entry must have.
  The enumeration "HmiContextProviderType" can contain the following values:
  - NoContext = 0
  - Calendar = 1
    For "IContextDefinition" instances generated by the PI Option Calendar.
  - PerformanceInsightMachineState = 2
    For "IContextDefinition" instances generated by the PI Option Performance Insight.
  - LineCoordinator = 3
    For "IContextDefinition" instances generated by the PI Option Line Coordinator.
  - UserDefined = 5
    It is a user-defined "IContextDefinition" instance, created by ODK, for example.
- `plantViewPath`:
  [in]: Path to an "IPlantObject" instance
  E.g.: ".hierarchy::PlantView/Ln_1/M_1"
  Is used in combination with `p_strContextName` for unique identification of the "IContextDefinition" instance.
- `endtime`:
  [in]: End time of the new context log entry

"Add" method

Adds a "IContextDefintion" instance to a vector. The methods Clear(), Subscribe() and CancelSubscription() can be called for the instances of the vector.

```
CRFESULT Add(CFSTR contextName, CFENUM type, CFSTR plantViewPath)
```

- `contextName`:
  [in]: The name of the "IContextDefintion" instance
- `type`:
  [in]: The HmiContextProviderType of the "IContextDefintion" instance
  The enumeration "HmiContextProviderType" can contain the following values:
  - NoContext = 0
  - Calendar = 1
    For "IContextDefinition" instances generated by the PI Option Calendar.
  - PerformanceInsightMachineState = 2
    For "IContextDefinition" instances generated by the PI Option Performance Insight.
  - LineCoordinator = 3
    For "IContextDefinition" instances generated by the PI Option Line Coordinator.
  - UserDefined = 5
    It is a user-defined "IContextDefinition" instance, created by ODK, for example.
- `plantViewPath`:
  [in]: Path to an "IPlantObject" instance
  E.g.: ".hierarchy::PlantView/Ln_1/M_1"
  Is used in combination with `contextName` for unique identification of the "IContextDefinition" instance.

"Clear" method

Deletes the "IContextDefintion" instances added via `Add()` from the vector.

```
CRFESULT Clear()
```

"Subscribe" method

Subscribes the "IContextDefinition" instances added to the vector via `Add()` for monitoring.

```
CRFESULT Subscribe(IContextLoggingCallBack* pContextLoggingCallback)
```

- `pContextLoggingCallback`:
  [in]: Points to the "IContextLoggingCallBack" object that implements the callback interface.

"CancelSubscribe" method

Unsubscribes the "IContextDefinition" instances added to the vector with `Add()` from monitoring.

```
CRFESULT CancelSubscribe()
```

Examples

Copying code

```

IContextLoggingCallBack

Description

The C++ interface "IContextLoggingCallBack" defines methods for implementing asynchronous operations for monitoring "IContextDefinition" instances. The methods are used by the "IContextLogging" interface.

The interface implements the methods of the "ICfUnknown" interface.

All methods return CF_SUCCESS after successful execution. In the case of an error, the methods return the corresponding error code.

Members

"OnCreate" method

Callback method is called when a ContextDefintion is created in the database by calling the "IContextLogging.CreateContextDefinitions" method.

```
CFRESULT OnCreate(uint32_t globalError, CFSTR SystemName,
IContextErrorEnumerator* errors, CFBOOL Completed)
```

- `globalError`:
  [in]: Global ErrorCode when a global error occurs during the call. All other parameters are invalid in this case.
- `SystemName`:
  [in]: Name of the system on which the ContextDefinitions have been created.
- `errors`:
  [in]: Enumerator for the instance-specific errors that were created when the ContextDefinitions were created.
- `Completed`:
  [in]: Status of the asynchronous transfer:
  - True: All ContextDefinitions have been notified.
  - False: Additional notifications are expected.

Members "OnRead"

Callback method is called:

- When a ContextDefintion is read from the database by calling the "IContextLogging.ReadContextDefinitions" method.
  The method with the following signature is called:
  `CFRESULT OnRead(uint32_t globalError, CFSTR SystemName, IContextDefinitionEnumerator* contextLoggingResult, CFBOOL Completed)`
  - `globalError`:
    [in]: Global ErrorCode when a global error occurs during the call. All other parameters are invalid in this case.
  - `SystemName`:
    [in]: Name of the system on which the ContextDefinitions have been created.
  - `contextLoggingResult`:
    [in]: Enumerator for the read "IContextDefinition" instances
  - `Completed`:
    [in]: Status of the asynchronous transfer:
    True: All ContextDefinitions have been notified.
    False: Additional notifications are expected.
- When a LoggedContext is read by calling the "IContextLogging.ReadContexts" method.
  The method with the following signature is called:
  `CFRESULT OnRead(uint32_t globalError, CFSTR SystemName, ILoggedContextEnumerator* loggedContexts, CFBOOL Completed)`
  - `globalError`:
    [in]: Global ErrorCode when a global error occurs during the call. All other parameters are invalid in this case.
  - `SystemName`:
    [in]: Name of the system on which the "ILoggedContext" instances have been created.
  - `contextLoggingResult`:
    [in]: Enumerator for the read "ILoggedContext" instances that were started or stopped.
  - `Completed`:
    [in]: Status of the asynchronous transfer:
    True: All ContextDefinitions have been notified.
    False: Additional notifications are expected.
  - `Completed`:
    [in]: Status of the asynchronous transfer:
    True: All ContextDefinitions have been notified.
    False: Additional notifications are expected.

"OnDataChanged" method

Callback method is called when a monitored "ILoggedContext" instance is started or stopped by calling "IContextLogging.StartContext" or "IContextLogging.StopContext".

```
CFRESULT OnDataChanged(ILoggedContextEnumerator* pEnumerator)
```

- `pEnumerator`:
  [out]: Points to an "ILoggedContextEnumerator" object which contains an enumeration with "ILoggedContext" instances.

IContextDefinitionEnumerator

Description

The C++ interface "IContextDefinitionEnumerator" specifies methods for handling the enumeration of "IContextDefinition" instances. The enumeration is returned by the "OnRead" method of an "IContextLoggingCallBack" instance.

The interface inherits from the "ICfUnknown" interface.

All methods return CF_SUCCESS after successful execution. In the case of an error, the methods return the corresponding error code.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(IContextDefinition **pItem)
```

- `ppItem`
  [out]: The current "IContextDefinition" instance

"Reset" method

Reset the current position in the enumeration. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumeration or the number of its elements.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of "IContextDefinition" instances

IContextErrorEnumerator

Description

The C++ interface "IContextErrorEnumerator" specifies methods for handling the enumeration of "IContextError" instances. The enumeration is returned by the "OnCreate" method of an "IContextLoggingCallBack" instance.

The interface inherits from the "ICfUnknown" interface.

All methods return CF_SUCCESS after successful execution. In the case of an error, the methods return the corresponding error code.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(IContextError **pItem)
```

- `ppItem`
  [out]: The current "IContextError" instance

"Reset" method

Reset the current position in the enumeration. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumeration or the number of its elements.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of "IContextError" instances

ILoggedContextEnumerator

Description

The C++ interface "ILoggedContextEnumerator" specifies methods for handling the enumeration of "ILoggedContext" instances. The enumeration is returned by the "OnRead" method of an "IContextLoggingCallBack" instance.

The interface inherits from the "ICfUnknown" interface.

All methods return CF_SUCCESS after successful execution. In the case of an error, the methods return the corresponding error code.

Members

"MoveNext" method

Go to the next element of the enumeration.

```
CFRESULT MoveNext()
```

"Current" method

Output the current element of the enumeration.

```
CFRESULT Current(ILoggedContext **pItem)
```

- `ppItem`
  [out]: The current "ILoggedContext" instance

"Reset" method

Reset the current position in the enumeration. The "MoveNext" method moves afterwards to the first element.

```
CFRESULT Reset()
```

"Count" method

Output the size of the enumeration or the number of its elements.

```
CRFESULT Count(uint32_t* pCount)
```

- `pCount`
  [out]: Number of "ILoggedContext" instances

IContextDefinition

Description

The C++ interface "IContextDefinition" specifies properties for defining "IContextDefinition" instances. "ILoggingContext" instances can be created using the StartContext() and StopContext() methods based on an "IContextDefiniton" instance.

The interface implements the methods of the "ICfUnknown" interface.

All methods return CF_SUCCESS after successful execution. In the case of an error, the methods return the corresponding error code.

Members

"GetPlantViewPath" method

Sets the path to the plant object of the "IContextDefinition" instance.

```
CRFESULT GetPlantViewPath(CFSTR* p_strPlantViewPath)
```

- p_strPlantViewPath:
  [out]: The path to the plant object
  Example: ".hierarchy::Plant/Station"

"SetPlantViewPath" method

Sets the path to the plant object of the "IContextDefinition" instance.

```
CRFESULT SetPlantViewPath(CFSTR p_strPlantViewPath)
```

- p_strPlantViewPath:
  [in]: The path to the plant object
  Example: ".hierarchy::Plant/Station"

"GetProviderType" method

The source that creates the instance.

Is used together with "Name" to uniquely identify a "IContextDefinition" instance.

```
CRFESULT GetProviderType(CFENUM* pContextType)
```

- pContextType:
  [out]: The enumeration "HmiContextProviderType" can contain the following values:
  - NoContext = 0
  - Calendar = 1
    For "IContextDefinition" instances generated by the PI Option Calendar.
  - PerformanceInsightMachineState = 2
    For "IContextDefinition" instances generated by the PI Option Performance Insight.
  - LineCoordinator = 3
    For "IContextDefinition" instances generated by the PI Option Line Coordinator.
  - UserDefined = 5
    It is a user-defined "IContextDefinition" instance, created by ODK, for example.

"GetName" method

Supplies the name of the "IContextDefinition" instance.

```
CRFESULT GetName(CFSTR* pName)
```

- pName:
  [out]: The name

"SetName" method

Sets the name of the "IContextDefinition" instance.

Sets the name of the "IContextDefinition" instance.

```
CRFESULT SetName(IN CFSTR name)
```

- name:
  [in]: The name

"GetDisplayNames" method

Supplies the display name of the "IContextDefinition" instance

```
CRFESULT GetDisplayNames(ICfMapIDToVariant** ppDisplayName)
```

- `ppDisplayName`:
  [out]: The display name

"SetDisplayNames" method

Sets the display name of the "IContextDefinition" instance.

```
CRFESULT SetDisplayNames(ICfMapIDToVariant* pDisplayName)
```

- `pDisplayName`:
  [in]: The display name

"GetDataType" method

Supplies the data type of the "IContextDefinition" instance.

```
CRFESULT GetDataType(HmiContextDataType* pdatatype)
```

- `pdatatype`:
  [out]: The data type
  The enumeration "HmiContextDataType" can contain the following values:
  - Bool = 0x01
  - SInt = 0x02
  - Int = 0x03
  - DInt = 0x04
  - LInt = 0x05
  - USInt = 0x06
  - UInt = 0x07
  - UDInt = 0x08
  - ULInt = 0x09
  - Real = 0x0A
  - LReal = 0x0B
  - LTime = 0x0C
  - DateTime = 0x0D
  - Byte = 0x11
  - Word = 0x12
  - DWord = 0x13
  - LWord = 0x14
  - String = 0x32

"SetDataType" method

Sets the data type of the "IContextDefinition" instance.

```
CRFESULT SetDataType(HmiContextDataType datatype)
```

- `datatype`:
  [in]: The data type
  The enumeration "HmiContextDataType" can contain the following values:
  - Bool = 0x01
  - SInt = 0x02
  - Int = 0x03
  - DInt = 0x04
  - LInt = 0x05
  - USInt = 0x06
  - UInt = 0x07
  - UDInt = 0x08
  - ULInt = 0x09
  - Real = 0x0A
  - LReal = 0x0B
  - LTime = 0x0C
  - DateTime = 0x0D
  - Byte = 0x11
  - Word = 0x12
  - DWord = 0x13
  - LWord = 0x14
  - String = 0x32

"GetErrorCode" method

Supplies the error code of the "IContextDefinition" instance

```
CRFESULT GetErrorCode(uint32_t* error)
```

- `error`:
  [out]:

Examples

Copy code

```
void DisplayContextDefinition(const std::vector<IContextDefinitionPtr>& ContextDef)
{
   for (auto& pValues : ContextDef)
   {
      uint32_t ErrorCode;
      pValues->GetErrorCode(&ErrorCode);
      CCfString strName;
      pValues->GetName(&strName);
      CFENUM pnum;
      pValues->GetProviderType(&pnum);
      HmiContextDataType dataType;
      pValues->GetDataType(&dataType);
      ICfMapIDToVariantPtr displayName;
      pValues->GetDisplayNames(&displayName);
      uint32_t nCount;
      displayName->Count(&nCount);
      for (uint32_t nIndex = 0; nIndex < nCount; nIndex++)
      {
         int32_t langID;
         displayName->KeyAt(index, &langID);
         CCfVariant vtName;
         displayName->ValueAt(langID, &vtName);
      }
      CCfString strPlantViewPath;
      pValues->GetPlantViewPath(&strPlantViewPath);
   }
}
```

ILoggedContext

Description

The C++ interface "ILoggedContext" defines properties of context log entries of an "IContextDefinition" instance.

The context log entries are started and stopped using methods of the "IContextLogging" interface.

The interface implements the methods of the "ICfUnknown" interface.

All methods return CF_SUCCESS after successful execution. In the case of an error, the methods return the corresponding error code.

Members

"GetStartTime" method

Supplies the start time of the "IContextLogging" instance.

```
CRFESULT GetStartTime(CFDATETIME64* value)
```

- `value`:
  [out]: The start time

"GetEndTime" method

Supplies the end time of the "IContextLogging" instance.

```
CRFESULT GetEndTime(CFDATETIME64* value)
```

- `value`:
  [out]: The end time

"GetErrorCode" method

Supplies the error code of the "IContextLogging" instance.

```
CRFESULT GetErrorCode(uint32_t* error)
```

- `error`:
  [out]: The error code

"GetValue" method

Supplies the value of the "IContextLogging" instance. The value has the same data type as is specified by the "DataType" property of the "IContextDefinition" instance.

Example: An "IContextDefinition" instance has the name "Product" and the data type String. Its "IContextLogging" instance has the value "Limo".

```
CRFESULT GetValue(CFVARIANT * value)
```

- `value`:
  [out]: The name of the "IContextDefinition" instance in the user interface

"GetQuality" method

Supplies the QualityCode of the context value.

```
CRFESULT GetQuality(uint32_t* quality)
```

- `quality`:
  [out]: The QualityCode

Examples

Copy code

```
void DisplayContext(const std::vector<ILoggedContextPtr>& Context)
{
   for (const auto& item : Context)
   {
      uint32_t pError;
      item->GetErrorCode(&pError);
      CCfDateTime64 dtStartTime;
      item->GetStartTime(&dtStartTime);
      CCfString strStartTime = dtStartTime.GetDateTimeString();
      CCfDateTime64 dtEnd;
      item->GetEndTime(&dtEnd);
      CCfString strEndTime = dtEnd.GetDateTimeString();
      uint32_t pQuality;
      item->GetQuality(&pQuality);
      CCfString name;
      item->GetName(&name);
      CCfString viewPath;
      item->GetPlantViewPath(&viewPath);
      CFENUM providerType;
      item->GetProviderType(&providerType);
      CCfVariant vtValue;
      item->GetValue(&vtValue);
      PrintVariantType(vtValue);
   }
}
```

IContextError

Description

The C++ interface "IContextError" specifies methods for accessing error results that occur when creating ContextDefinitions in the database.

The interface implements the methods of the "ICfUnknown" interface.

All methods return CF_SUCCESS after successful execution. In the case of an error, the methods return the corresponding error code.

Members

"GetContextName" method

Supplies the name of the "IContextDefintion" instance.

```
CRFESULT GetContextName(CFSTR* p_strName)
```

- `p_strName`:
  [out]: The name

"GetContextErrorCode" method

Supplies the error code.

```
CRFRESULT GetErrorCode)(OUT uint32_t* p_ErrorCode)
```

- `p_ErrorCode`:
  [out]: The error code

Examples

Copy code

```
void DisplayContextError(const std::vector<IContextErrorPtr>& pVecContext)
{
   for (const auto& pContext : pVecContext)
   {
      CCfString strContextName;
      pContext->GetContextName(&strContextName);
      uint32_t value;
      pContext->GetErrorCode(&value);
}
```

IContextFilter

Description

The C++ interface "IContextFilter" defines methods for accessing properties of "IContextDefinition" instances, according to whose "ILoggedContext" instances are to be filtered.

The interface inherits from the "ICfUnknown" interface.

All methods return CF_SUCCESS after successful execution. In the case of an error, the methods return the corresponding error code.

Members

"GetName" method

Supplies the name of the "IContextDefinition" instance according to whose "ILoggedContext" instances the filtering is performed.

```
CFRESULT GetContextName(CFSTR* p_strName)
```

`p_strName`:

[out]: The name of the "IContextDefinition" instance

"SetName" method

Sets the name of the "IContextDefinition" instance according to whose "ILoggedContext" instances the filtering is performed.

```
CFRESULT SetContextName( CFSTR p_strName)
```

`p_strName`:

[in]: The name of the "IContextDefinition" instance

"GetProviderType" method

The HmiContextProviderType that the "IContextDefinition" instance of the context log entry must have.

```
CFRESULT GetProviderType(CFENUM* p_ProviderType)
```

- `p_ProviderType`:
  [out]: The provider type.
  The enumeration "HmiContextProviderType" can contain the following values:
  - NoContext = 0
  - Calendar = 1
    For "IContextDefinition" instances generated by the PI Option Calendar.
  - PerformanceInsightMachineState = 2
    For "IContextDefinition" instances generated by the PI Option Performance Insight.
  - LineCoordinator = 3
    For "IContextDefinition" instances generated by the PI Option Line Coordinator.
  - UserDefined = 5
    It is a user-defined "IContextDefinition" instance, created by ODK, for example.

"SetProviderType" method

Sets the HmiContextProviderType of an "IContextDefinition" instance for whose "ILoggedContext" instances the filtering is performed.

```
CFRESULT SetProviderType(CFENUM p_ProviderType)
```

- `p_ProviderType`:
  [in]: The provider type.
  The enumeration "HmiContextProviderType" can contain the following values: See "GetProviderType".

"GetOperator" method

Supplies the filter operator.

```
CFRESULT GetOperator(CFSTR* p_Operator)
```

- `p_Operator`:
  [out]: The operator.
  The operator is applied to the value.

"SetOperator" method

Sets the filter operator.

```
CFRESULT SetOperator(CFSTR p_Operator)
```

- p_Operator:
  [in]: The operator
  The operator is applied to the value. The following operators are allowed:
  For values with data type Int and Real:
  - =
  - !=
  - <
  - >
  - <=
  - >=

  For values with data type String:
  - LIKE
  - =

  Strings must always be fully specified.

"GetValue" method

Supplies the "Value" of the "ILoggedContext" instance

```
CFRESULT GetValue(CFVARIANT* p_vtValue)
```

- p_vtValue:
  [out]: The value

"SetValue" method

Sets the "Value" of the "ILoggedContext" instance

```
CFRESULT SetValue(CFVARIANT p_vtValue)
```

- p_vtValue:
  [in]: The value

20.3.10 Reference of the ODK error codes

Reference

Below you will find an overview of the error codes and error descriptions of the ODK interface.

General errors

Error name	Error code	Error description
OPN_E_GENERAL_FAILED	2147496936	General error occurred.
OPN_E_GENERAL_CONNECT_FAILED	2147496967	Connection to runtime failed.
OPN_E_GENERAL_TYPE_NOT_SUPPORTED	2147496985	The type isn't supported.
OPN_E_GENERAL_UNKNOWN_NAME	2147496986	The given name is unknown.
OPN_E_GENERAL_LOADING_FAILED	2147496987	The option can't be loaded.
OPN_E_GENERAL_RESPONSE_TIMEOUT	2147496951	The operation has timed out.
OPN_E_GENERAL_NOT_IMPLEMENTED	2147496954	Error Description Not Availbale
OPN_E_GENERAL_INVALID_SYSTEM	2147498006	Invalid system name.
OPN_E_GENERAL_REQUEST_REJECTED	2147496981	Your request has been rejected.
OPN_E_GENERAL_LICENSE_MISSING	2147496988	There are missing or expired Licenses.
OPN_E_GENERAL_LICENSE_COMPROMISED	2147496989	License: The Module integrity has been compromised.
OPN_E_GENERAL_LICENSE_DISCONNECTED	2147496990	The License is disconnected.

Tag errors

Error name	Error code	Error description
OPN_E_TAG_FAILED	2148545512	General error in Tag model occurred.
OPN_E_TAG_INVALIDARG	2148545513	Invalid arguments passed to function.
OPN_E_TAG_ACCESS_DENIED	2148545532	No access
OPN_E_TAG_INVALIDCREF	2148545514	Invalid CRef found during conversion.
OPN_E_TAG_INVALIDOBJECTSTATE	2148545515	Object not properly initialized.
OPN_E_TAG_NOTSUPPORTED	2148545516	Function not supported.
OPN_E_TAG_OUTOFRANGE	2148545517	The given value is out of range.
OPN_E_TAG_NOTEXISTING	2148545518	The given tag does not exist.
OPN_E_TAG_WRITE_FALS	2148545545	The write operation was partly successful
OPN_E_TAG_READ_FALSE	2148545546	The read operation was partly successful
OPN_E_TAG_DUPLICATE_CREF	2148545549	Duplicate CRef found during conversion.
OPN_E_TAG_INVALID_POINTER	2148545550	Function returned an invalid pointer
OPN_E_TAG_CONVERSION_NOT_ALLOWED	2148545551	Conversion not allowed
OPN_E_TAG_PLC_NOT_CONNECTED	2148545552	PLC not connected
OPN_E_TAG_PLC_PROTOCOL_ERROR	2148545553	Error Description Not Availbale
OPN_E_TAG_INVALID_SUBSCRIPTION	2148545554	Invalid tag subscription
OPN_E_TAG_NO_INIT	2148545519	HmiRuntime not properly initialized.
OPN_E_TAG_UNSUPPORTED_VALUE_TYPE	2148545560	Unsupported value type
OPN_E_TAG_EXISTS	2148545521	The given tag already exists

Error name	Error code	Error description
OPN_E_TAGSET_ALREADY_SUBSCRIBED	2148545610	The TagSet already Subscribed
OPN_E_EMPTY_COLLECTION_SUBSCRIPTION	2148545611	No Tags to Subscribe

Alarm errors

Error name	Error code	Error description
OPN_E_ActiveAlarm_FAILED	2149594088	General error in Alarm model occurred.
OPN_E_ActiveAlarm_INVALID_SUBSCRIPTION	2149594130	Invalid alarm subscription
OPN_E_ActiveAlarm_INVALIDARG	2149594089	Invalid arguments passed to function.
OPN_E_ActiveAlarm_NOINIT	2149594095	HmiRuntime not properly initialized.
OPN_E_ActiveAlarm_INVALIDCREF	2149594090	Invalid CRef found during conversion.
OPN_E_ActiveAlarm_INVALIDOBJECTSTATE	2149594091	Object not properly initialized.
OPN_E_ActiveAlarm_WRONGALARMSTATE	2149594096	The active alarm can't be acknowledged or reset in current state.
OPN_E_ActiveAlarm_INVALID_POINTER	2149594126	Function returned an invalid pointer
OPN_E_ActiveAlarm_NOT_EXISTING	2149594094	The given alarm does not exist.
OPN_E_ActiveAlarm_DUPLICATE_CREF	2149594125	Dublicate CRef found during conversion.
OPN_E_ActiveAlarm_CREATE_FAILED	2149594098	Alarm Create Failed
OPN_E_ActiveAlarm_TIMEOUT	2149594103	Response TimeOut

Plant model errors

Error name	Error code	Error description
OPN_E_CPM_FAILED	2151691240	General error in PlantModel model occurred.
OPN_E_CPM_INVALIDARG	2151691241	Invalid arguments passed to function.
OPN_E_CPM_NODE_NOT_FOUND	2151691275	PlantModel Node Not Exists
OPN_E_CPM_NODEMEMBER_NOT_FOUND	2151691276	PlantModel Node Member Not Exists
OPN_E_CPM_INVALID_POINTER	2151691278	Function returned an invalid pointer
OPN_E_CPM_NO_MEMORY	2151691283	Function returned null pointer
OPN_E_CPM_INVALID_OBJECT_STATE	2151691243	Object not properly initialized.
OPN_E_CPM_UNKNOWN_IDENTIFIER	2151691284	Function returned unknow identifier
OPN_E_CPM_REQUEST_REJECTED	2151691285	Method returned request rejected
OPN_E_CPM_INVALID_CREF	2151691242	Invalid CRef found during conversion.
OPN_E_CPM_INVALID_SUBSCRIPTION	2151691282	Invalid PlantModel node subscription
OPN_E_CPM_NO_INIT	2151691247	HmiRuntime not properly initialized.

Connection errors

Error name	Error code	Error description
OPN_E_CONNECTION_INVALID_PARAM-ETERS	2154837060	Invalid arguments passed to function.
OPN_E_CONNECTION_CONNEC-TION_LOST	2154837061	Connection lost
OPN_E_CONNECTION_INVALID_CREF	2154837062	Invalid connection name passed to func-tion
OPN_E_CONNECTION_INVALID_POINT-ER	2154837063	Invalid pointer
OPN_E_CONNECTION_NOT_EXISTING	2154837064	The connection with the given name does not exist.
OPN_E_CONNECTION_FAILED	2154837065	General error in connection model oc-curred.

Context errors

Error name	Error code	Error description
OPN_E_CONTEXTLOGGING_CRE-ATE_FAILED	2162178060	Create Context Definition failed
OPN_E_CONTEXTLOGGING_TIMEOUT	2162177015	Request TimeOut
OPN_E_CONTEXTLOGGING_INVA-LID_PARAMETERS	2162177001	Invalid Arguments Passed
OPN_E_CONTEXTLOGGING_NOT_SUP-PORTED	2162177004	Not Supported
OPN_E_CONTEXTLOG-GING_START_FAILED	2162178061	Failed to start ContextLogging
OPN_E_CONTEXTLOGGING_FAILED	2162177000	General Error Occurred
OPN_E_CONTEXTLOGGING_NO_INIT	2162177007	Initialization Failed
OPN_E_CONTEXTLOGGING_OB-JECT_STATE	2162177003	Object State is Invalid or CHmiRuntime not properly initialized
OPN_E_CONTEXTLOG-GING_STOP_FAILED	2162178062	Failed to stop ContextLogging
OPN_E_CONTEXTLOG-GING_NODE_NOT_FOUND	2162177035	Plant node not found
OPN_E_CONTEXTLOGGING_DEFINI-TION_NOTEXISTS	2162177006	The given object doesn't exist
OPN_E_CONTEXTLOGGING_DEFINI-TION_EXISTS	2162177009	The given object already exist
OPN_E_CONTEXTLOGGING_SUBSCRIP-TION_EXITS	2162178063	There is already Open Subscription
OPN_E_CONTEXTLOGGING_SUBSCRIP-TION_NOT_OPEN	2162177042	There is no Open Subscription

20.4 WinCC Unified GraphQL

20.4.1 Introduction

WinCC Unified GraphQL API

GraphQL API is a web-based interface for implementing applications (GraphQL clients) that have read and write access to runtime data.

Functional scope

GraphQL enables access to the following runtime data of an HMI device:

	Read	Write	Subscribe to changes
Process values of tags	✓	✓	✓
Active alarms	✓	-	✓

Benefits

Use of Unified GraphQL clients offers the following benefits:

- High user-friendliness, easy integration and few dependencies
- Growing prevalence of GraphQL
- No installation of Unified Runtime on the developer device and when operating the client application
- GraphQL API can be used by all applications that access a network via HTTP and WebSockets (e.g. web applications, desktop applications, console applications).
- You can integrate ready-to-use GraphQL client libraries for a variety of programming languages into your project.
  You can easily extend these libraries through a user-defined GraphQL layer.
- There are ready-to-use GraphQL clients you can use to execute GraphQL operations without having to develop them yourself. An example is the Apollo client used in the quick start section of this user help.
- Built-in API documentation that is available online and always up-to-date
- Precise control of the client over the data processed and transferred by the server

Technical details

- HTTP and WebSockets are the transport layer for client operations and server responses.
- The operations and responses use a JSON-based format.
- The structure of client queries and server responses is described by a schema.
- Each operation specifies a selection set. Only the attributes specified in the selection set are contained in the server response.

20.4.2 Basics

20.4.2.1 Limitations

Unified GraphQL API is subject to the following limitations:

- Access is limited to the runtime to which the GraphQL client is logged in. Access to HMI devices connected via Runtime Collaboration is not possible.
- If a GraphQL client subscribes to two tags and their tag names are renamed in a delta download such that they swap their names, the subscription is closed.
  The GraphQL client must subscribe to the tags again.
- In the existing version of Unified GraphQL, several alarm properties cannot be used as a filter in `activeAlarms` subscriptions and `acitveAlarms` queries.
  For a list of these alarm properties, see section Filtering alarms (Page 8248).

20.4.2.2 Security

This section provides security-relevant information on the GraphQL server.

Secure communication via IIS web server

To ensure secure communication and to protect the GraphQL server and runtime, the GraphQL server is accessed via the IIS web server of Unified Runtime.

Direct access to GraphQL is not supported.

Session duration

A session between the GraphQL server and GraphQL client remains open as long as there is activity, e.g. a regularly executed query.

All sessions of all users are closed in the following cases:

- Start of the GraphQL server with a different manager number
- Deletion of the internal session database

Closing all sessions of a user

You have the following options:

- The user logs out from one of his sessions and, in so doing, passes the value `True` for parameter `allSessions`.
- The administrator changes the password of the user in the engineering system. The administrator logs in to GraphQL with the changed login data of the user. The administrator logs the user out and, in so doing, passes the value `True` for parameter `allSessions`.

20.4.2.3 More information

You can find more information on GraphQL here:

- About GraphQL in general: https://graphql.org/ (https://graphql.org/)
- About Apollo Studio: https://www.apollographql.com/ (https://www.apollographql.com/)
- Solutions to technical problems concerning GraphQL: https://stackoverflow.com/ (https://stackoverflow.com/)

20.4.3 Quick start

20.4.3.1 Purpose of this quick start

This quick start demonstrates, using a ready-to-use GraphQL client freely available in Apollo Studio, how to establish a connection to a Unified GraphQL server, log in to runtime and then query, manipulate and subscribe to runtime data.

The quick start sets you up for subsequent experimentation with the GraphQL client of Apollo and helps you to get started working with WinCC Unified GraphQL.

20.4.3.2 Requirements

To follow the instructions and examples of the quick start, the following general requirements must be met:

- WinCC Unified Runtime is installed on a PC.
- A runtime project is running on the PC.
- The GraphQL Server Manager on this PC is effective via IIS through: **https://localhost/graphql/**

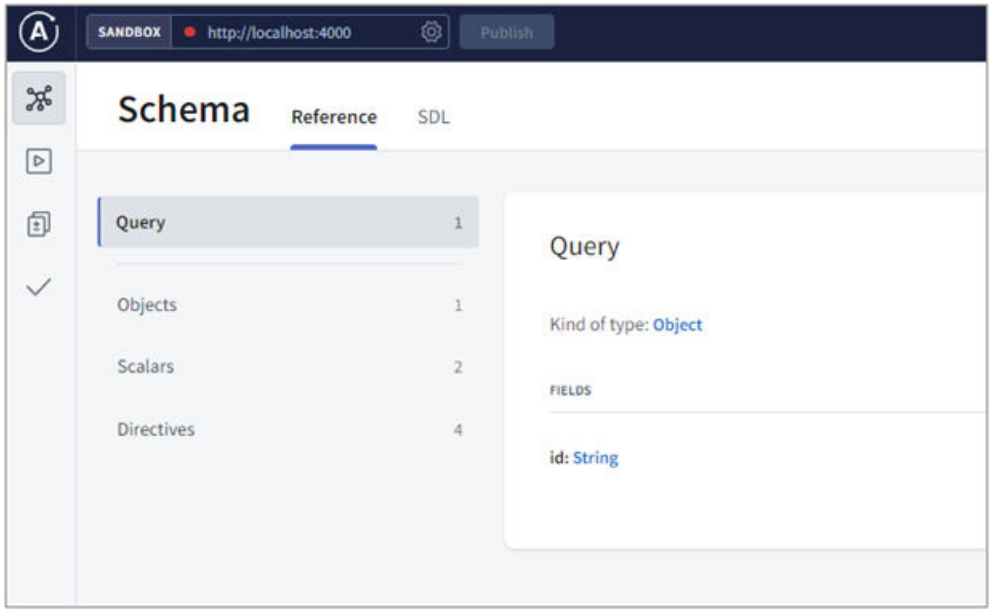
See also

Setting up the GraphQL client (Page 8224)

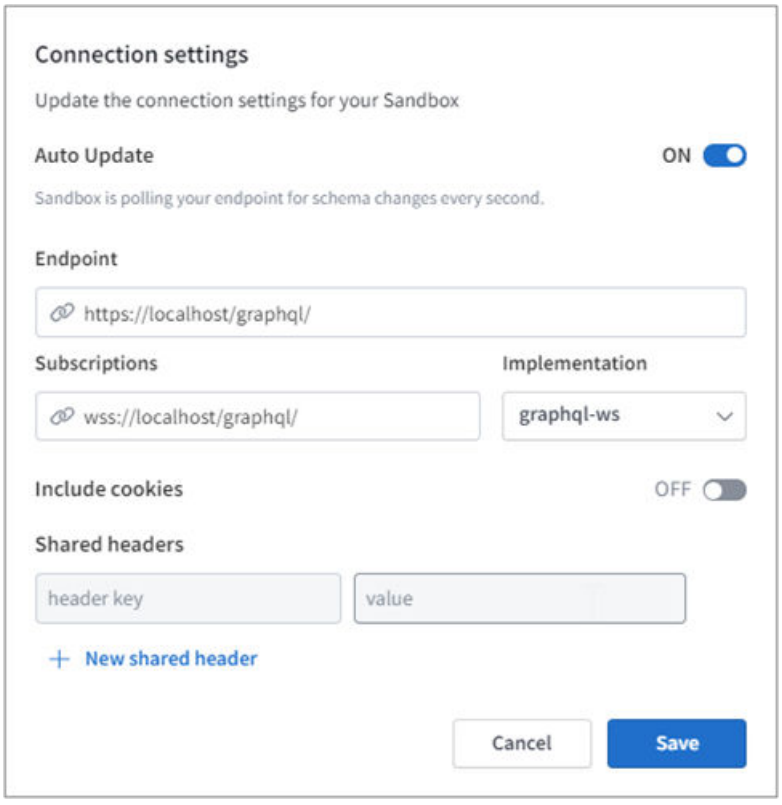
20.4.3.3 Setting up the GraphQL client

Procedure

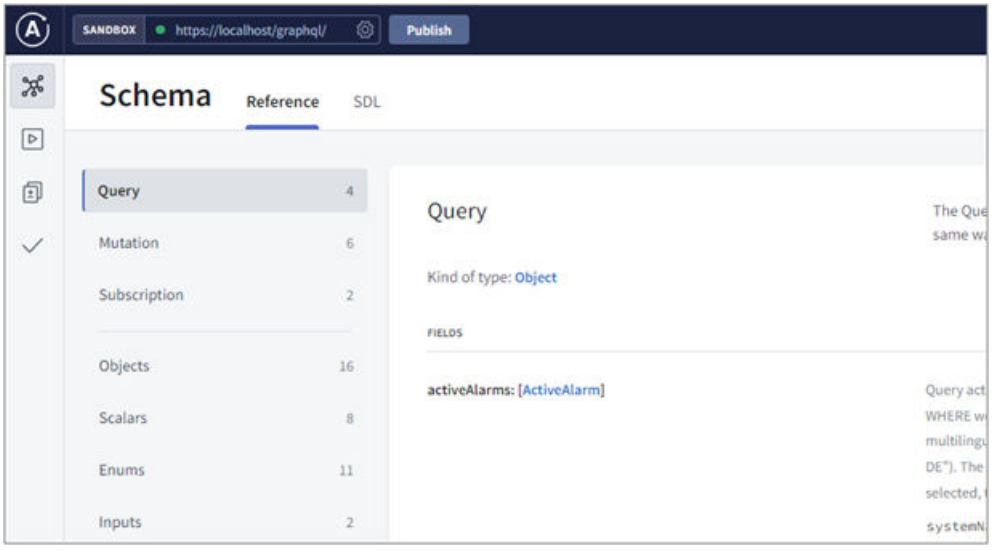
1. Start a web browser on a device that has access to the runtime server.
2. Enter the following address in the address line and press Enter:
   https://studio.apollographql.com/sandbox/explorer (https://studio.apollographql.com/sandbox/explorer)
   Apollo Studio opens:



3. Click on the gear icon in the address line.
   The configuration settings for the GraphQL client open. Apply the following settings:



Schema introspection is active for Unified GraphQL Server. That is why you see a green dot in the address line after configuration of the GraphQL client. In addition, the documentation of the GraphQL API is available in the client:



See also

Requirements (Page 8223)

Basics on the schema (Page 8234)

20.4.3.4 Logging in to the GraphQL server

Note

For information on the SWAC login, see section "loginSWAC" mutation (Page 8251).

In order for a GraphQL client to access runtime data, it must be logged in to Runtime with a user.

Requirement

In addition to the general requirements, the following is required:

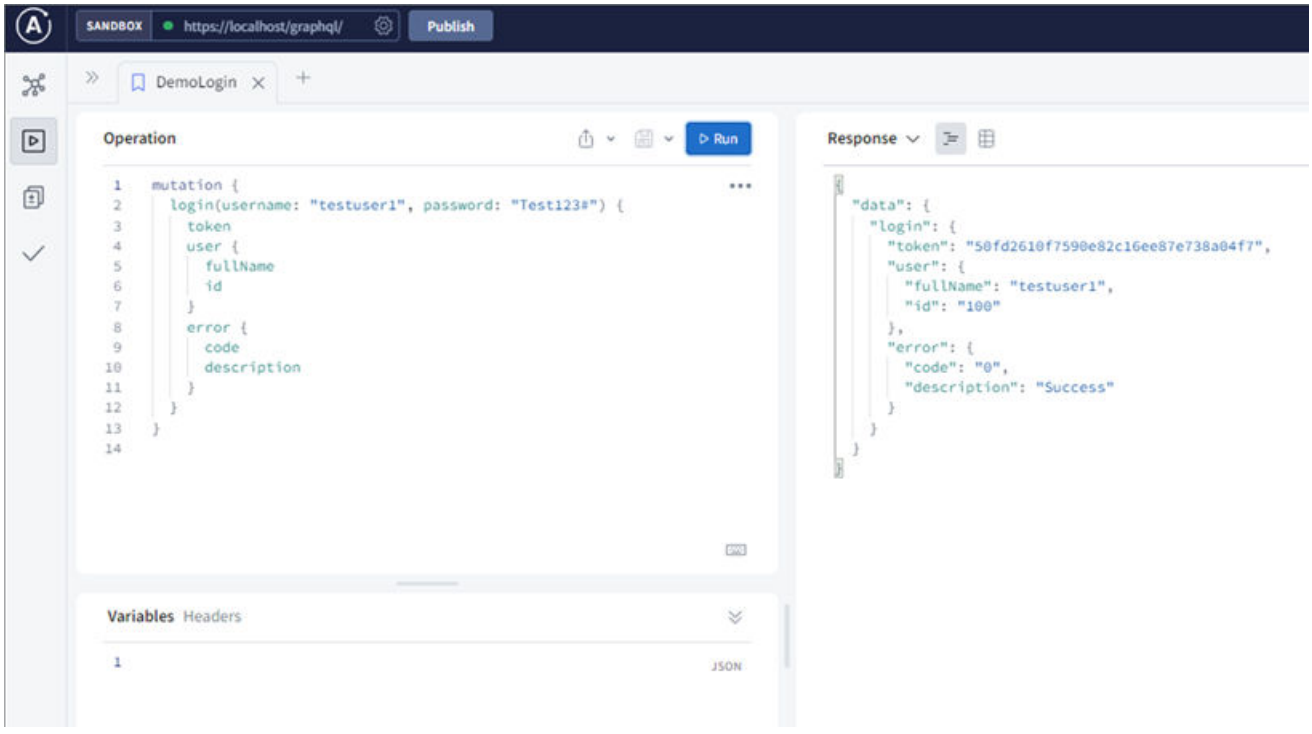
- The GraphQL server has been set up.

Procedure

1. Log the GraphQL client in to the GraphQL server by calling the mutation `login`, as shown below.
   Pass the login data of a UMC user configured for runtime to the operation as input parameter.

Result

The server opens a session. The server response contains the ID of the authorization token:



You use this token for subsequent requests of GraphQL operations. If the client has been inactive for a while, the token expires. The client must log in again.

Note

By requesting the `extendSession`mutation, you keep the session open in spite of inactivity.

See also

Requirements (Page 8223)

Setting up the GraphQL client (Page 8224)

Authorizing an operation request (Page 8231)

"login" mutation (Page 8250)

"extendSession" mutation (Page 8252)

20.4.3.5 Executing a GraphQL operation

Requirement

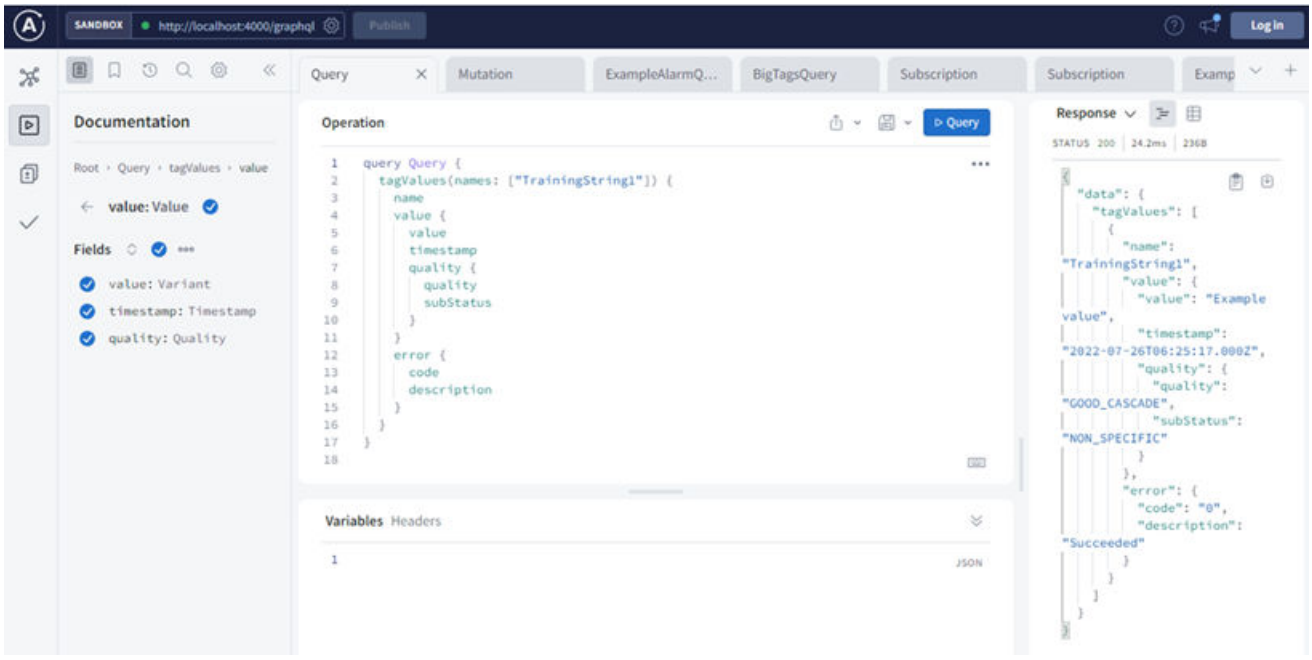
In addition to the general requirements, the following is required:

- The GraphQL server has been set up.
- The GraphQL client is logged in to the server. The authorization token issued at login is still valid.
- The user with whom the GraphQL client is logged in has the following function rights:
  - Query or subscription: "GraphQL - read access" or "GraphQL - read/write access"
  - Mutation: "GraphQL - read/write access"

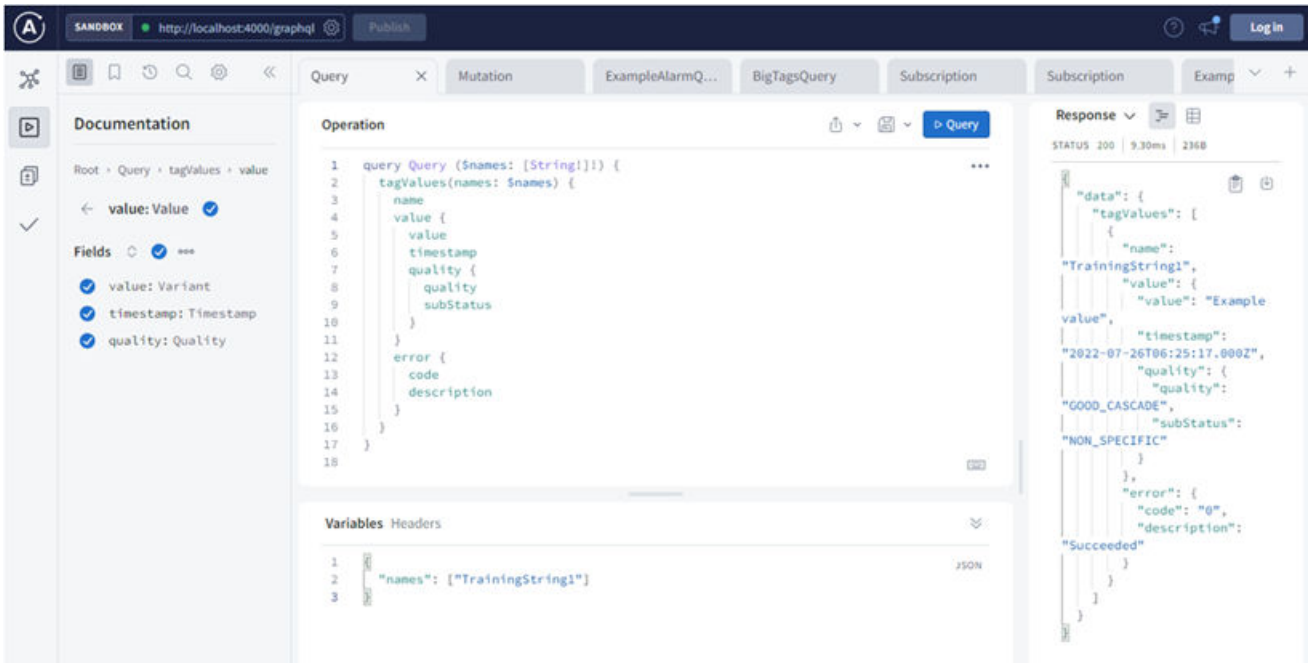
Procedure

To execute GraphQL operations for a Unified GraphQL client, proceed as described below. The basic procedure is the same for all three operation types.

1. In Apollo Studio, select the Explorer view and input the desired operation in the "Operation" panel.
   You have the following options:
   - Manually entering the operation request in the panel
   - Pointing the mouse to the desired position in the panel, changing to the Documentation view, selecting the desired operation there and adding it with the "+" icon
2. Specify the input parameters.
   You have the following options:
   - Manually passing the parameters in the operation request:



– Creating a tag in the "Variables" panel and using it in the "Operation" panel. For this you enter the character "$" followed by the tag name in the "Operation" panel:



Note

Tag as input parameter

Ensure that the tag exists in the connected runtime and that the tag name is written correctly.

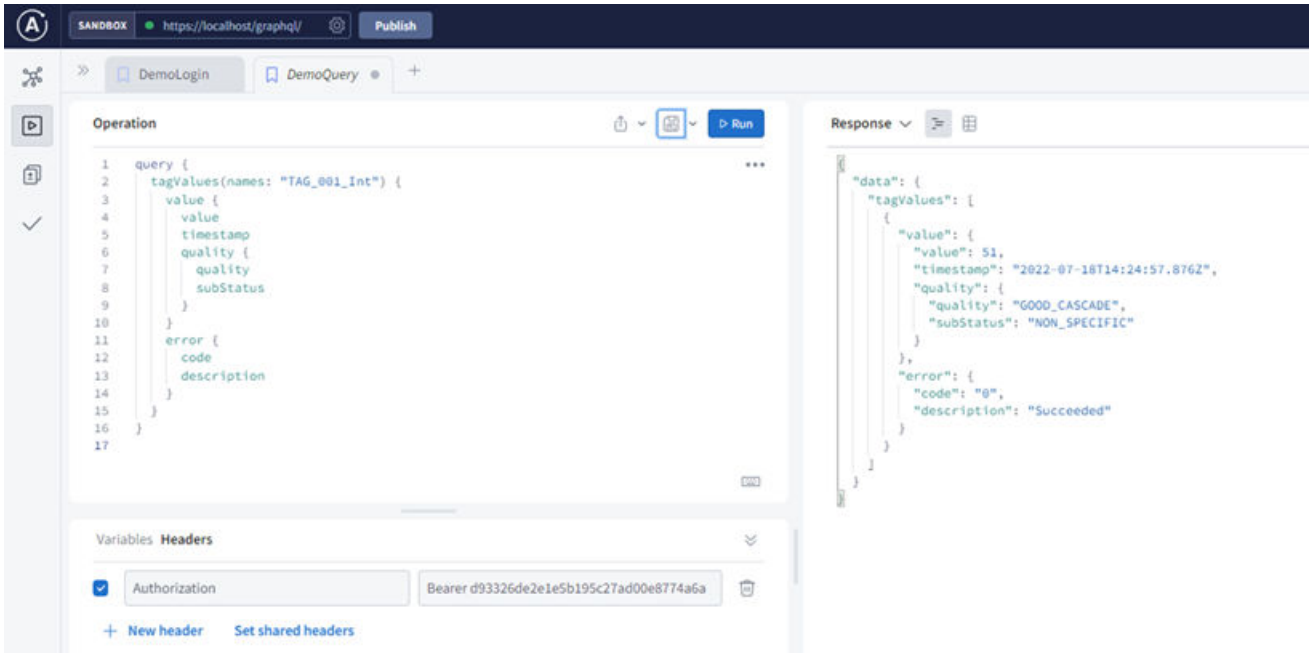
3. In the "Headers" panel, define additional HTTP header values, e.g. obligatory authorization tokens for access to tags and active alarms.
4. Click the button for executing the operation.

Result

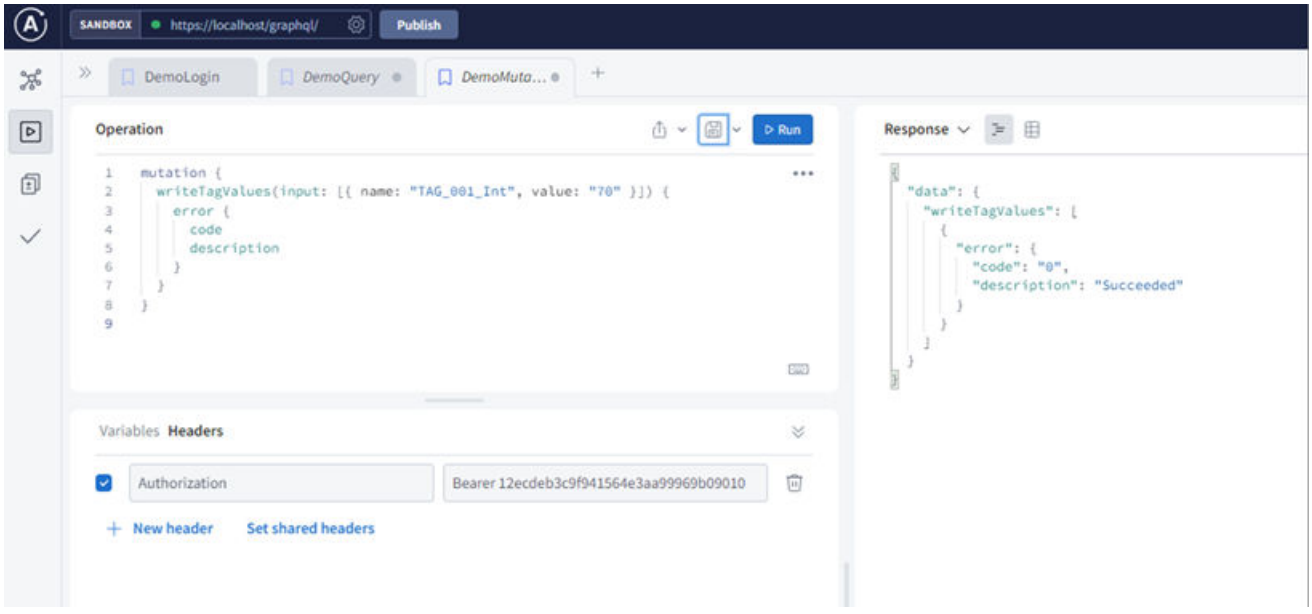
- The operation is executed.
- If the client is logged in, you see the response of the GraphQL server in the "Response" panel. If the client is not logged in, you see a corresponding error message in the "Response" panel.

Examples for the various operation types

- Query type:

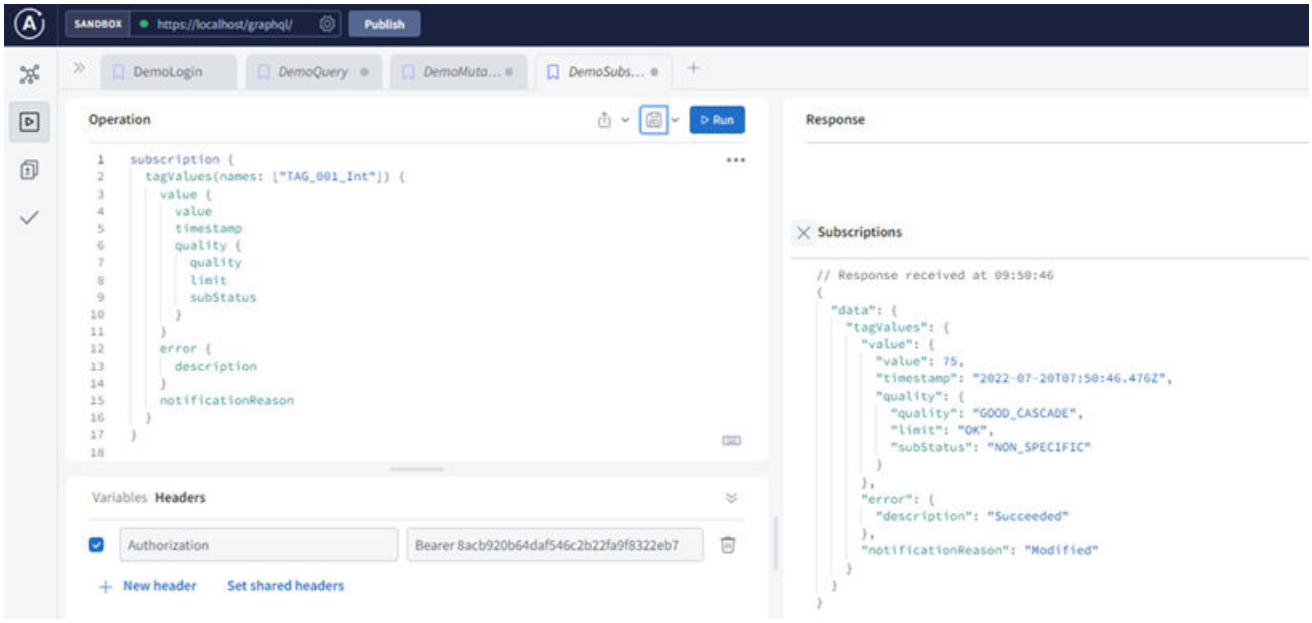


- Mutation type:



If you execute a query for the tag after the mutation, you receive the modified value.

- Subscription type:



If you execute a mutation for the tag after the subscription, you receive a notification.

Closing a subscription

To close a subscription, click "X" button in the "Subscriptions" panel.

Note

Subscriptions in Apollo Studio

There is only one active subscription in the GraphQL client in Apollo Studio. If you start a second subscription, it replaces the first one. The second subscription is then the active subscription.

See also

Requirements (Page 8223)

Authorizing an operation request (Page 8231)

20.4.3.6 Authorizing an operation request

Requirement

In addition to the general requirements, the following is required:

- The GraphQL server has been set up.
- The GraphQL client is logged in to the server. The authorization token issued at login is still valid.
- The desired operation is displayed in the "Operation" panel.

Procedure

1. Select the "Headers" panel of the operation.
2. Add a header if necessary.
3. Enter the following header data:
   - Key: "Authorization"
   - Value: "Bearer <Token ID from the login response>"
4. Activate the header.

Requirements (Page 8223)

Executing a GraphQL operation (Page 8227)

Logging in to the GraphQL server (Page 8226)

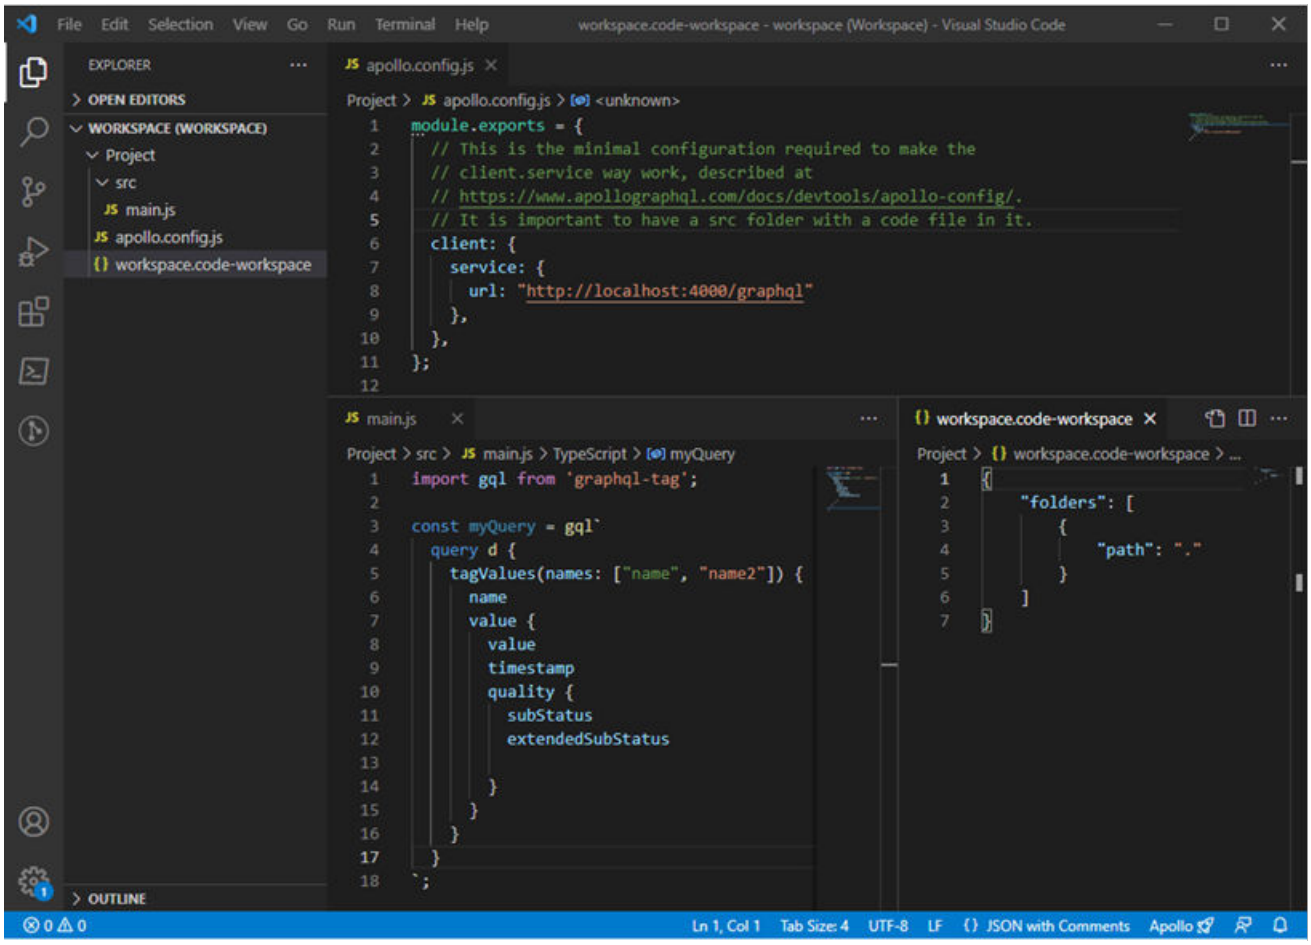
20.4.3.7 Using the syntax highlighting and autocompletion functions of Apollo

Introduction

This section describes how to integrate the Apollo GraphQL extension for syntax highlighting and autocompletion into Visual Studio Code.

Procedure

1. Download the Apollo GraphQL extension from the Visual Studio Marketplace (https://marketplace.visualstudio.com/items?itemName=apollographql.vscode-apollo).
2. Install it.
3. Apply the following settings:



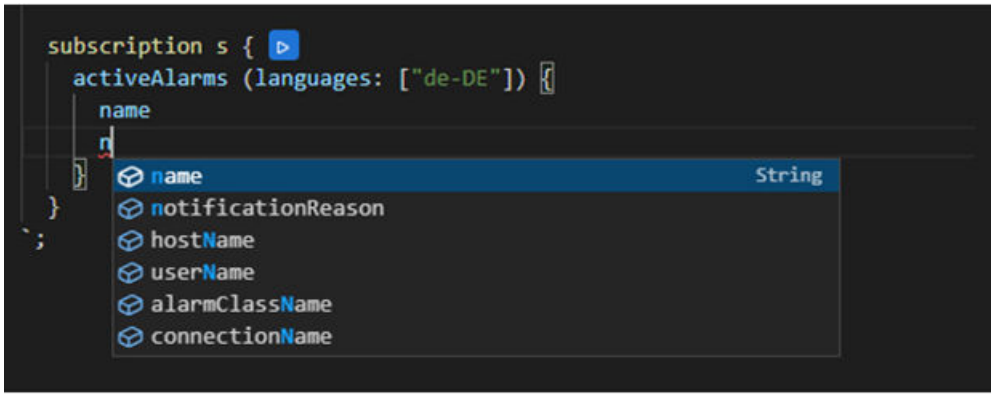
Result

When the schema inspection of the GraphQL server is active and the GraphQL server is running, Visual Studio supports you with additional features.

Example:

- Hover the mouse pointer over a GraphQL code. A tooltip with additional information opens:

- When entering GraphQL code, you receive autocomplete suggestions:



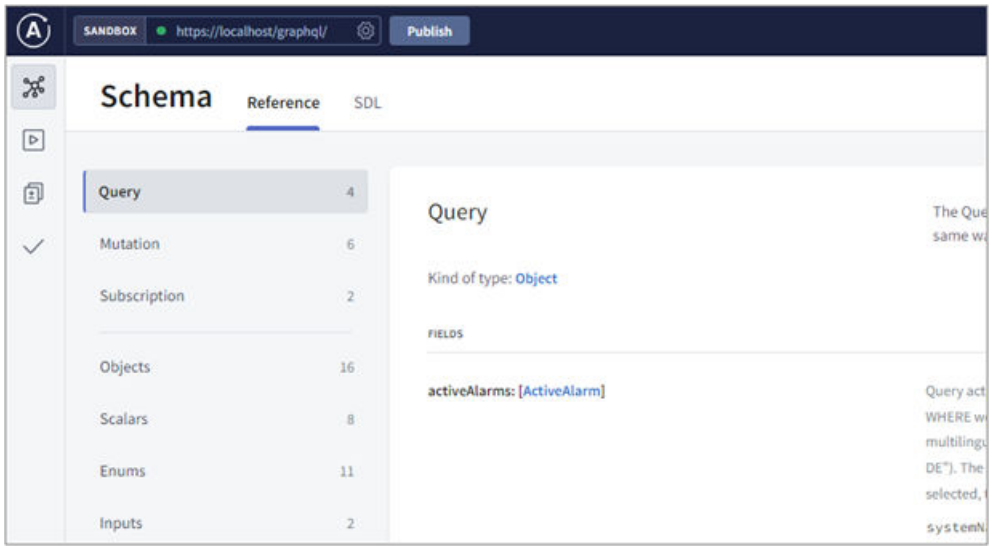
20.4.4 Schema

20.4.4.1 Basics on the schema

The GraphQL schema is an object in JSON format that describes the GraphQL API, which is understandable by humans and applications alike.

If the schema of the GraphQL server is known to the GraphQL client, the client supports you with autocompletion and syntax checking.

In Apollo Studio, you can see that the client knows the schema by the green dot in the address bar. The documentation of the GraphQL API is then available in the client:



Automatically querying the schema

The schema inspection is active for GraphQL server by default. Therefore, GraphQL clients automatically query the schema from the server.

Manually downloading the schema

You can also download the schema manually, e.g. by executing the following npx command in the Windows command line:

```
npx apollo-cli download-schema http://localhost:4000/graphql --
output schema.json
```

More information on the manual download of the schema can be found here (https://stackoverflow.com/questions/37397886/get-graphql-whole-schema-query).

Syntax highlighting and autocompletion in editors

To make use of syntax highlighting and autocompletion in editors when implementing a GraphQL client, extensions suitable for the development environment must be installed. For example, you can install the Apollo GraphQL extension for Visual Studio Code.

See also Using the syntax highlighting and autocompletion functions of Apollo (Page 8232).

20.4.4.2 Structure of a client query

Overview

```
1 query
2 {
3    tagValues(names: "DEMO_CPU_TEMPERATURE")
4    {
5       value
```

```
6       {
7          value
8          timestamp
9          quality
10          {
11             quality
12          }
13       }
14       error
15       {
16          code
17          description
18       }
19    }
20 }
```

Line	Description
1	The operation type of the requested operation, in this example: `query`
3	Name of the requested operation and list of input parameters in the following format: (<Name_Parameter1>: "<Value>", <Name_Parameter2>: "<Value>")
4 to 19	The selection set with the attributes requested from the server

Structure of the selection set

The selection set is where you specify for the operation request which attributes the server returns. You can request all the attributes defined in the return type of the operation.

Notation:
`Operation name ( <Input parameter>) {<Selection set> }`

Where <Selection set> stands for a comma-separated list of the attribute names requested by the server.

Specification of type-based attributes:
<Name of type-based attribute> { <Comma-separated list of attribute names> }

Example of type-based attributes: The attributes `value`, `quality` and `error` from the selection set above.

20.4.5 Reference of GraphQL API

20.4.5.1 General information on GraphQL API

An important feature of GraphQL API is its high user-friendliness. For Unified GraphQL API, this means:

- Tags and active alarms from runtime are addressed using their name and not their ID. The names are configured in the engineering.
- QualityCodes are represented by the string assigned to them in an enumeration. This improves readability of the code.

- Color values are translated to the standard RGBA notation.
- Date information is represented according to ISO 8601 (https://en.wikipedia.org/wiki/ISO_8601).
- To execute bulk operations, it is possible to pass GraphQL operations as input parameter lists. The operation is then applied to each list element.
- Internal error messages are translated into user-level messages.

20.4.5.2 GraphQL operation types

Overview

GraphQL operations have one of the following operation types:

- Query
- Mutation
- Subscription

Queries

You use queries for read operations. The query sends an HTTPS request to the GraphQL server.

Example: Querying tag values or alarms that satisfy a filter criterion

Mutations

You use mutations for write operations. The mutation sends a one-time query to the GraphQL server.

Example: Writing the value and QualityCode of the value to a tag

Subscriptions

You use subscriptions so that your GraphQL client can react to runtime events promptly without having to continually query the runtime status. The subscription creates a permanent WebSocket connection between the GraphQL server and client. When a client subscribes to an alarm or tag, the server notifies the client when changes to the alarm or tag are active.

Example: The GraphQL client is to execute a certain operation when the value of a tag changes.

Subscriptions are usually closed by the client, but they can also be closed by the server or mutually by both sides, e.g. in the event of a network failure.

Subscriptions use the graphql-transport-ws protocol. Configure this protocol for your GraphQL library or implement WebSocket communication based on this protocol.

Client-side GraphQL libraries provide different options for closing subscriptions, depending on the programming language being used. For example, Python uses an asynchronous iterator that the notification runs through. When the loop is exited, the subscription is closed.

See also

Disconnection by server (Page 8266)

20.4.5.3 Operations for tags

"tagValues" query

Requirements

- The user who is logged in to runtime for the GraphQL client has the rights "GraphQL - read access" or "GraphQL - read/write access" in runtime.

Description

```
tagValues(names: [String]): [TagValueResult]
```

Operation name	`tagValues`
Operation type	`query`
Function	Reads the tags specified in input parameter `names`. Read access is possible to tags with a simple data type, as well as to elements of structure tags and arrays with a simple data type.
Input parameters	`names` • Mandatory parameter • Data type: String • List of names of the tags whose properties you want to read. Notation: `names:["<Name Tag1>", "<Name Tag2>", "<...>"]` Example: `names:["motor1.tempMax", "motor1.tempMin"]` Addressing of tags: – Addressing a tag with simple data type: `<Tag name>` – Addressing an element of a structure tag: `<Structure tag name>.<Element name>` Example: `motor1.speed` – Addressing an individual element of an array: `<Array name>[<Index>]` Example: `FloatArrayTag[0]` – Address all tags of an array: `<Array name>` Example: `FloatArrayTag` The tags are returned in an array in the response.
Selection set	Mandatory specification Specify which attributes the server returns for the queried tags. You can request the attributes defined in the `TagValueResult` type. For information on the notation, see section Structure of a client query (Page 8235).

Server response	Supplies the attributes requested in the selection set for all tags specified with `names` as key-value pairs of a JSON data record.
Error messages (`code: description`)	• `0: Success` • `2: Cannot resolve provided name` • `202: Only leaf elements of a Structure Tag can be addressed`

Example

```
queryExampleTagQuery{
  tagValues(names:["ExampleTagName1", "ExampleTagName2"]){
    name
    value{
      value
      timestamp
      quality
      {
        quality
        subStatus
      }
    }
    error{
      description
      code
    }
  }
}
```

See also

"TagValueResult" type (Page 8261)

"writeTags" mutation

Requirements

- The user who is logged in to runtime for the GraphQL client has the right "GraphQL - read/write access" in runtime.

Description

```
writeTagValues(
      input: [TagValueInput],
      timestamp: Timestamp
      quality: QualityInput
    ): [WriteTagValuesResult]
```

Operation name	`writeTagValues`
Operation type	`mutation`
Function	Writes the tags specified in input parameter `input`. Write access is possible to tags with a simple data type, as well as to elements of structure tags and arrays with a simple data type. The mutation allows you to write multiple tags or multiple properties of the same tag with a single operation request.

Input parameters	`input`
	• Mandatory parameter
	• Data type: String
	• A list of the tags and values that you want to write
	Notation: `input:[ {<Information on tag 1>}, {<Information on tag 2>},{<...>}]`
	Example: `input: [{name: "motor1.speed", value: "100"}, {name: "motor2.speed", value: "140"}]`
	Make the following entries for each tag:
	– `name`: For addressing the tag
	Addressing a tag with simple data type: `<Tag name>`
	Addressing an element of a structure tag: `<Structure tag name>.<Element name>`
	Example: `motor1.speed`
	Addressing an individual element of an array: `<Array name>[<Index>]`
	Example: `FloatArrayTag[0]`
	It is not possible to address all elements of an array together.
	– `value`: The process value that is written to the tag
	The data type of the passed value must be convertible to the data type of the tag.
	– (Optional) `timestamp`: The time stamp of the process value as `Timestamp`[1]
	– (Optional) `quality`: The QualityCode of the process value as `QualityInput`
	`timestamp`
	• Optional
	Written to all tags from `input` for which no time stamp has been passed.[1]
	If the input parameter is empty, the current system time is used as the time stamp.
	• Data type: `Timestamp`
	`quality`
	• Optional
	Written to all tags from `input` for which no QualityCode has been passed.
	If the input parameter is empty, "GOOD" is used as QualityCode.
	• Data type: `QualityInput`

Selection set	Mandatory specification Specify which attributes the server returns for the written tags. You can request the attributes defined in the `WriteTagValueResult` type. For information on the notation, see section Structure of a client query (Page 8235).
Server response	Supplies the attributes requested in the selection set for all tags specified with `input` as key-value pairs of a JSON data record.
Error messages (`code: description`)	• `0: Success` • `2: Cannot resolve provided name` • `201: Cannot convert provided value to data type` • `202: Only leaf elements of a Structure Tag can be addressed`

[1] The timestamp must be newer that the current timestamp of the tag and must not be in the future.

Example

```
mutation ExampleTagValueWrite {
  writeTagValues(input:[
    {
      name:"ExampleStringTag",
      value: "Example value text”
    },
    {
      name:"ExampleIntegerTag",
      value: 42,
      timestamp:"2022-07-26T06:25:15Z"
    }
  ], quality:{quality: GOOD_NON_CASCADE}){
    name
    error{
      code
      description
    }
  }
}
```

See also

"WriteTagValueResult" type (Page 8263)

"QualityInput" type (Page 8259)

"tagValues" subscription

Requirements

- The user who is logged in to runtime for the GraphQL client has the rights "GraphQL - read access" or "GraphQL - read/write access" in runtime.

Description

```
tagValues(names: [String]): TagValueNotification
```

Operation name	`tagValues`
Operation type	subscription
Function	Subscribes the tags specified in input parameter `names`.
Input parameters	`names` • Mandatory parameter • Data type: String • List of names of the tags whose properties you want to subscribe to. Notation: `names:["<Name Tag1>", "<Name Tag2>", "<...>"]` Addressing of tags: – Address an element of a structure tag: `<Name of the structure tag>.<Name of the element>` – Address a single element of an array: `<Name of the array>[<Index>]` Example: `FloatArrayTag[0]` – Address all tags of an array: `<Name of the array>` Example: `FloatArrayTag` The tags are returned in an array in the response.
Selection set	Mandatory specification Specify which attributes the server returns for the subscribed tags. You can request the attributes defined in the `TagValuesNotification` type. For information on the notation, see section Structure of a client query (Page 8235). Recommendation: Request `name` and `notifcationReason`.
Server response	Until the subscription is closed, supplies an initial notification for the subscribed tags with the current values of the attributes requested in the selection set as key-value pairs of a JSON data record, and supplies subsequent notifications when a subscribed tag changes.
Error messages (`code: description`)	• `0: Success` • `2: Cannot resolve provided name` • `202: Only leaf elements of a Structure Tag can be addressed`

Closing a subscription

The subscription of a tag closes implicitly:

- When the tag is renamed.
- When the tag is deleted.

When you close the subscription in the GraphQL client explicitly, all previously subscribed tags are no longer subscribed.

Example

```
subscriptionSubscription{
  tagValues(names:["Example_Tag_1", "Example_Tag_2"]){
    name
    value{
      value
      timestamp
      quality{
        quality
        substatus
      }
    }
    error{
      code
      description
    }
    notificationReason
  }
}
```

See also

"TagValueNotification" type (Page 8260)

20.4.5.4 Operations for alarms

"activeAlarms" query

Requirements

- The user who is logged in to runtime for the GraphQL client has the rights "GraphQL - read access" or "GraphQL - read/write access" in runtime.

Description

```
activeAlarms(
      systemNames: [String]
      filterString: String
      filterLanguage: String
```

```
    languages: [String]
  ): [ActiveAlarm]
```

Operation name	`activeAlarms`
Operation type	`query`
Function	Queries the active alarms from the server.

Input parameters	`systemNames`
	• Optional
	• Data type: String
	• Reserved for future versions.
	• Specifies the runtime whose alarms are queried.
	In the current version, the queried alarms are always the alarms of the runtime connected to the GraphQL server.
	`filterString`
	• Optional
	• Data type: String
	• Defines filter criteria for the alarms. See section Filtering alarms (Page 8248).
	If you do not define a filter, the server returns all alarms active in runtime.
	`filterLanguage`
	• Optional
	• Data type: String
	• When `filterString` uses a string with a translatable alarm property, you use `filterLanguage` to define which language is used for the comparison.[1]
	• Default value: "en-US"
	`languages`
	• Optional
	• Data type: String array
	• Defines the languages in which the server returns the texts of translatable alarm properties and the order of the requested languages.[1]
	Example:
	`queryLanguageExample { activeAlarms(languages:["en-US", "de-DE"] { name, eventText, alarmText1, alarmClassName, state, raiseTime, priority } }`
	The server response supplies the attributes specified in the selection set for the queried alarms. Translatable properties, such as `eventText`, are each returned in a string array. The element with index 0 always contains the English text and the element with index 1 the German text.
	• Default value: "en-US"

Selection set	Mandatory specification Specify which attributes the server returns for the queried alarms. You can request the attributes defined in the `ActiveAlarm` type. For information on the notation, see section Structure of a client query (Page 8235).

Server response	Supplies the attributes requested in the selection set for the queried alarms as key-value pairs of a JSON data record.
Error messages (`code` and `description`)	• `0: Success` • `301: Syntax error in query string` • `302: At least one of the requested languages is invalid` • `303: The provided filter language is invalid`

[1] Languages must be specified in ISO language code format (e.g. "en-US", "de-DE"). Note that the entry is case-sensitive.

Example

```
queryExampleAlarmQuery
{
   activeAlarms(languages:["en-US", "de-DE"],
     filterLanguage:"en-US",
     filterString:(raiseTime <= '2022-07-26T09:00' AND userName
LIKE '* Doe') OR priority > 2")
     {
         name
         eventText
         alarmText1
         alarmClassName
         state
         raiseTime
         priority
     }
}
```

"ActiveAlarm" and "ActiveAlarmNotification" types (Page 8254)

"Error" type (Page 8258)

"activeAlarms" subscription

Requirements

- The user who is logged in to runtime for the GraphQL client has the rights "GraphQL - read access" or "GraphQL - read/write access" in runtime.

Description

```
activeAlarms(
      systemNames: [String]
      filterString: String
      filterLanguage: String
      languages: [String]
    ): ActiveAlarmNotification
```

Operation name	`activeAlarms`
Operation type	`subscription`
Function	Subscribes to active alarms.

Input parameters	`systemNames`
	• Optional
	• Data type: String
	• Reserved for future versions.
	• Specifies the runtime whose alarms are subscribed to.
	In the current version, the queried alarms are always the alarms of the runtime connected to the GraphQL server.
	`filterString`
	• Optional
	• Data type: String
	• Defines filter criteria for the alarms. See section Filtering alarms (Page 8248).
	If you do not define a filter, you subscribe to all alarms active in runtime.
	`filterLanguage`
	• Optional
	• Data type: String
	• When `filterString` uses a string with a translatable alarm property, you use `filterLanguage` to define which language is used for the comparison.[1]
	• Default value: "en-US"
	`languages`
	• Optional
	• Data type: String array
	• Defines the languages in which the server returns the texts of translatable alarm properties and the order of the requested languages.[1]
	Example:
	`queryLanguageExample { activeAlarms(languages:["en-US", "de-DE"] { name, eventText, alarmText1, alarmClassName, state, raiseTime, priority } }`
	The initial notification and the subsequent notifications supply the attributes specified in the selection set for the subscribed alarm. Translatable properties, such as `eventText`, are each returned in a string array. The element with index 0 always contains the English text and the element with index 1 the German text.

Selection set	Mandatory specification Specify which attributes the server returns for the subscribed alarms. You can request the attributes defined in the `ActiveAlarmNotification` type. For information on the notation, see section Structure of a client query (Page 8235). Recommendation: Request `name` and `notifcationReason`.

Server response	Until the subscription is closed, the server sends an initial notification and sends subsequent notifications when an attribute of one of the subscribed alarms specified in the selection set changes. The notifications contain the current values of the attributes requested in the selection set as key-value pairs of a JSON data record.
Error messages (`code` and `description`)	• `0: Success` • `301: Syntax error in query string` • `302: At least one of the requested languages is invalid` • `303: The provided filter language is invalid`

[1] Languages must be specified in ISO language code format (e.g. "en-US", "de-DE"). Note that the entry is case-sensitive.

Example

```
queryExampleAlarmQuery
{
   activeAlarms(languages:["en-US", "de-DE"],
     filterLanguage:"en-US",
     filterString:(raiseTime <= '2022-07-26T09:00' AND userName
LIKE '* Doe') OR priority > 2")
     {
         name
         notificationReason
         eventText
         alarmText1
         alarmClassName
         state
         raiseTime
         priority
     }
}
```

"Error" type (Page 8258)

"ActiveAlarm" and "ActiveAlarmNotification" types (Page 8254)

Filtering alarms

Introduction

You use input parameters of `activeAlarms` queries and `activeAlarms` subscriptions to define filters that control which alarms are read or subscribed to. This improves the performance of your GraphQL clients.

Limitation

In the current version of Unified GraphQL, you cannot filter by the following alarm properties:

- `state`
- `stateMachine`
- `changeReason`
- `sourceType`
- `suppressionState`
- `invalidFlags`
- `producer`
- `userResponse`
- `textColor`
- `backColor`
- `valueQuality`
- `quality`

Input parameter "filterString"

You use input parameter `filterString` to define the filter criteria. The filter string corresponds to the WHERE part of a valid ChromQueryLanguage string with addition of the keyword WHERE.

Note

ChromQueryLanguage (QCL) is based on SQL. You can also use most of the valid, simple SQL expressions in CQL.

Wildcards permitted in `filterString`:

*	Replaces any number of characters.
?	Replaces exactly 1 character.

Operators permitted in `filterString`:

>
>
=

LIKE	
()	For grouping of expressions
AND	For logically combining expressions
OR	

Note

Filtering by the "path" property

`path` is the full name of the alarm. It has the following components:

- Alarm of a tag: <System name>::<Tag name>:<Alarm name>
- Alarm of an element of a structure tag or array: <System name>::<Tag name>.<Element path>:<Alarm name>
  Delimiter for the components of the element path: "."

If the GraphQL client only has access to one runtime system or you want to query the alarms of all connected systems, you can replace the system name with the wildcard "*".

Input parameter "filterLanguage"

If `filterString` uses a translatable alarm property, use input parameter `filterLanguage` to specify the language of the text.

Specify the language in ISO language code format (e.g. "en-US", "de-DE"). Note that the entry is case-sensitive.

Examples

- `filterString: "alarmClassName = 'SystemNotification'"`
  Returns all active alarms with alarm class "SystemNotification".
- `filterString: "(raiseTime <= '2022-07-26T09:00' AND userName LIKE '* Doe') OR priority > 2"`
  Returns all alarms that were active before 2022-07-26 9:00 and whose associated user has the last name "Doe" or whose priority is greater than 2.
- `filterString: "eventText LIKE 'Maximum value exceeded'"` and `filterLanguage: "en-US"`
  The response returns only alarms that have the value "`Maximum value exceeded`" for `eventText` in English.

  Note

  You specify the languages and the order in which the texts of the translatable alarm properties are returned with input parameter `languages` in the operation request.

- `filterString: "path LIKE '*::motor1.currentSpeed:*'"`
  Supplies all active alarms of the `currentSpeed` element of the `motor1` structure tag.

20.4.5.5 Other operations

"login" mutation

Requirements

- The login data of a UMC user configured for runtime is known.

Description of "login"

```
login (
     username: String
     password: String
   ): Session
```

Operation name	`login`
Operation type	mutation
Function	Logs the GraphQL client in to the GraphQL server with the login data of a UMC user configured for Runtime. The user remains logged in until the session is closed, the user is logged out or the connection is disconnected.

Input parameters	`username`
	• Mandatory parameter
	• Data type: String
	• The user name of a UMC user configured for Runtime
	`password`
	• Mandatory parameter
	• Data type: String
	• The password of the UMC user

Selection set	Mandatory specification Specify which attributes the server returns. You can request the attributes defined in the `Session` type. For information on the notation, see section Structure of a client query (Page 8235). Request at least `token`. You require `token` for subsequent server requests. You pass `token` in the HTTP header `Authorization`, with appended `Bearer` prefix.
Server response	Supplies the attributes of the `Session` instance requested in the selection set as key-value pairs of a JSON data record.
Error messages (`code: description`)	• `0: Success` • `101: Incorrect credentials provided` • `102: UMC error`

See also

Disconnection by server (Page 8266)

"extendSession" mutation (Page 8252)

Logging in to the GraphQL server (Page 8226)

"Session" type (Page 8260)

"loginSWAC" mutation

Requirements

- The login data of a UMC user configured for runtime is known.
- The GraphQL client obtained a valid `Nonce` instance by calling `nonce` from the server.
- The GraphQL client has logged in to UMC with its user name and password and transmitted the nonce to UMC when logging in. In response, UMC sent a claim with a built-in nonce as well as a signed claim with a built-in nonce with a private key.

Description of "loginSWAC"

```
loginSWAC(
      claim: String
      signedClaim: String
    ): Session
```

Operation name	`loginSWAC`
Operation type	mutation
Function	Transmits the claim and signed claim that the GraphQL client received when logging in to UMC to the GraphQL server. When the `Nonce` contained in `claim` or `signedClaim` is valid, the client is logged on to the server. The user remains logged in until the session is closed, the user is logged out or the connection is disconnected.

Input parameters	`claim`
	• Mandatory parameter
	• Data type: String
	• The claim submitted by UMC.
	`signedClaim`
	• Mandatory parameter
	• Data type: String
	• The SignedClaim submitted by UMC.

Selection set	Mandatory specification Specify which attributes the server returns. You can request the attributes defined in the `Session` type. For information on the notation, see section Structure of a client query (Page 8235). Request at least `token`. You require `token` for subsequent server requests. You pass `token` in the HTTP header `Authorization`, with appended `Bearer` prefix.

Server response	Supplies the attributes requested in the selection set of the `Session` instance generated for the login as key-value pairs of a JSON data record.
Error messages (`code: description`)	• `0: Success` • `101: Incorrect credentials provided` • `103: Nonce expired`

"nonce" query (Page 8253)

"Nonce" type (Page 8258)

Disconnection by server (Page 8266)

"extendSession" mutation

Requirement

- The GraphQL client is logged in to the server with a valid UMC user.

Description

```
extendSession: Session
```

Operation name	`extendSession`
Operation type	mutation
Description	Extends the session of the GraphQL client. Call the operation to prevent clients that are mainly waiting for notifications from a subscription, for example, from becoming inactive and having to log in again.
Input parameters	-
Selection set	Mandatory specification Specify which attributes the server returns. You can request the attributes defined in the `Session` type. For information on the notation, see section Structure of a client query (Page 8235).
Server response	Supplies the attributes of the `Session` instance requested in the selection set as key-value pairs of a JSON data record.
Error messages (`code: description`)	-

See also

"login" mutation (Page 8250)

"Session" type (Page 8260)

"session" query

Requirement

- The GraphQL client is logged in to the server.

Description

```
session(
      allSessions: Boolean
    ): [Session]
```

Operation name	`session`
Operation type	query
Description	Queries the current session data from the server.
Input parameters	`allSessions` • Optional • Data type: Bool • Default: False: • True: The server sends the data for all sessions of the logged-in user.
Selection set	Mandatory specification Specify which attributes the server returns. You can request the attributes defined in the `Session` type. For information on the notation, see section Structure of a client query (Page 8235).
Server response	Supplies the attributes of the `Session` instance or instances requested in the selection set as key-value pairs of a JSON data record.
Error messages (`code: description`)	-

See also

"Session" type (Page 8260)

"nonce" query

Description

```
nonce: Nonce
```

Operation name	`nonce`
Operation type	`query`
Function	Queries a `Nonce` instance from the GraphQL server. The nonce is required for the SWAC login.
Input parameters	-

Selection set	Mandatory specification Specify which attributes the server returns. You can request the attributes defined in the `Nonce` type. For information on the notation, see section Structure of a client query (Page 8235). Request `value`.
Server response	Supplies the attributes of the `Nonce` instance requested in the selection set as key-value pairs of a JSON data record.
Error messages (`code: description`)	• `0: Success` • `101: Incorrect credentials provided` • `103: Nonce expired`

20.4.5.6 Reference for Unified-specific types and enumerations

Introduction

This section describes the Unified data types used in the GraphQL client queries and server responses.

For information about the enumerations used in these types, see the interface documentation that is available online when schema introspection is enabled.

"ActiveAlarm" and "ActiveAlarmNotification" types

Description

Instances of the type `ActiveAlarm` represent the information about alarms that you can request in `activeAlarms` queries from the server. Instances of type `ActiveAlarmNotification` represent information that you can request through `activeAlarm` subscriptions.

This includes:

- Properties of active alarms
  The table below provides a reference for the alarm properties.
  Translatable properties are returned as a string array. The array contains the alarm property texts in the languages requested and the order defined with input parameter `languages` in the operation request.
- The `languages` attribute
  A string array with the languages that the user has specified with input parameter `languages` in the `activeAlarms` request.
  For correct processing of the strings returned in the arrays for translatable alarm properties.

Reference of the alarm properties

The following table lists the alarm properties provided in the `ActiveAlarm` and `ActiveAlarmNotification` types in alphabetical order:

Name	Data type	Description
`acknowledgmentTime`	`Timestamp`	`Timestamp` instance for the time at which the alarm was acknowledged
`alarmClassID`	`Int`	User-defined ID of the alarm class of the alarm
`alarmClassName`	`String`	Name of the alarm class of the alarm
`alarmClassSymbol`	`[String]`	The symbols configured for the alarm class Translatable property
`alarmGroupID`	`Int`	User-defined ID of the alarm group to which alarm belongs
`alarmParameterValues`	`[Variant]`	To dynamize the following texts: `alarmText1` to `alarmText9` these values can be used as parameters in these texts.

`alarmText1`
`bis`
`alarmText9`
	`[String]`	Additional texts for the alarm
		Translatable properties

`alarmType`	`[String]`	Supplies details regarding the alarm condition. The values can be user-defined or product-specific. Translatable property
`area`	`String`	Name of the area to which the alarm belongs
`backColor`	`Color`	Background color of the alarm in the alarm control
`changeReason`	`[AlarmChangeReason]`	Reason for changes to the alarm as defined in enumeration `AlarmChangeReason`
`clearTime`	`Timestamp`	`Timestamp` instance for the time at which the alarm became inactive
`connectionName`	`String`	Only for PLC alarms Name of the HMI connection
`deadBand`	`Variant`	Hysteresis for `valueLimit` for suppressing the noise component during alarm generation
`duration`	`Timespan`	The time interval between the time when the alarm became active and the time when the alarm state changed the last time
`eventText`	`[String]`	Main text for the alarm, typically describes the cause of the alarm Translatable property
`flashing`	`Boolean`	True: The alarm flashes in the alarm control
`hostName`	`String`	Name of the device that hosts the source of the alarm In the case of alarms triggered by operator input, this is the client on which the operator made the input.
`infoText`	`[String]`	More information for the operator, such as instructions or standard procedures for handling this alarm Translatable property
`instanceID`	`Int`	Alarm ID of the active alarm For unambiguous alarm identification of configured alarms that can have more than one active alarm instance at a time.
`invalidFlags`	`AlarmInvalidFlags`	`AlarmInvalidFlags` instance that indicates whether attributes or configuration of the alarm are invalid.

Name	Data type	Description
`loopInAlarm`	`String`	A script function that jumps to the screen that has triggered the alarm.
`loopInAlarmParameterValues`	`Variant`	Parameters for loop-in-alarms
`modificationTime`	`Timestamp`	`Timestamp` instance for the last time one of the properties of the alarm was changed
`name`	`String`	Name of the configured alarm
`notificationReason`	`String`	Only for `ActiveAlarmNotification` Reason for the notification Possible values: • "Added" An active alarm was added to the subscription. • "Modified" A subscribed alarm was modified. • "Removed" A subscribed alarm was removed from the subscription because it became inactive or no longer satisfies the filter criteria.
`origin`	`String`	Name of the object that activated this alarm instance, e.g. an HMI device or function block.
`path`	`String`	The full alarm name Can be used for filtering the `activeAlarm` query or subscription. See section Filtering alarms (Page 8248).
`priority`	`Int`	The current priority of the active alarm Possible values: • 0: No priority assigned • 1-5: Low (primarily an informative function) • 6-10: Medium (warnings) • 11-15: High (errors) • 16: Highest (critical alarms)
`producer`	`AlarmProducer`	The Siemens product or the function of a domain to which the alarm source belongs, as defined in enumeration `AlarmProducer`
`quality`	`Quality`	Quality of `state` as `Quality` instance
`raiseTime`	`Timestamp`	`Timestamp` instance for the time at which the alarm became active
`resetTime`	`Timestamp`	`Timestamp` instance for the time at which the alarm was reset
`sourceID`	`String`	Identifies the source of the alarm instance For controller alarms, the communication driver assigns the ID based on the reference of the external alarm source, such as the alarm area ID of the S7 PLC. For application alarms, the application or the service assigns the ID so that the alarm has a relationship with a service-specific object, e.g. recipe name/ID by the service of the parameter set control.
`sourceType`	`AlarmSourceType`	Type of source from which the alarm was generated, e.g. tag-based, PLC-based or system-based, as defined in enumeration `AlarmSourceType`
`state`	`AlarmState`	The current state of the active alarm as defined in enumeration `AlarmState`

Name	Data type	Description
stateMachine	AlarmStateMachine	State machine of the active alarm The state machine defines possible states of the alarm and transitions between these states, as defined in enumeration AlarmStateMachine
stateText	[String]	The user-defined description of the alarm state Translatable property
suppressionState	AlarmSuppressionState	Visibility of the alarm Shelved alarms are not visible in the alarm control but are still active, as defined in enumeration AlarmSuppressionState
systemSeverity	Int	Alarm severity from the perspective of the system The number of severe alarms in a system provides an indication of the health of the system. In redundant systems, the healthier host becomes the active host and the less healthy host becomes the passive host.
textColor	Color	Text color of the alarm in the alarm control
userName	String	Name of the user associated with the last alarm event
userResponse	AlarmUserResponse	The expected operator response as defined in enumeration AlarmUserResponse
value	Variant	The value of the alarm
valueLimit	Variant	Limit for value as of which the alarm becomes active. If a dynamic limit has been configured for the alarm, then the updated limit
valueQuality	Quality	Quality of value as Quality instance

"Time span" type (Page 8261)

"Time stamp" type (Page 8262)

"Quality" type (Page 8259)

"AlarmInvalidFlags" type

Description

The AlarmInvalidFlags type defines attributes for invalid attributes or configurations of alarms.

Name	Data type	Description
invalidConfiguration	Boolean	The alarm has an invalid configuration.
invalidTimestamp	Boolean	The alarm has an invalid time stamp.

Name	Data type	Description
`invalidAlarmParameter`	`Boolean`	The alarm has an invalid alarm parameter.
`invalidEventText`	`Boolean`	The alarm has an invalid event text.

See also

"ActiveAlarm" and "ActiveAlarmNotification" types (Page 8254)

"Error" type

Description

The `Error` type defines the attributes of item-level errors.

For GraphQL operations with item-level errors, you can request these attributes from the server via the selection set when the operations call is made.

Attributes:

Name	Data type	Description
`code`	String	Numeric code of the error message
`description`	String	Detailed description of the error message

See also

Top-level and item-level errors (Page 8267)

"TagValueResult" type (Page 8261)

"WriteTagValueResult" type (Page 8263)

"TagValueNotification" type (Page 8260)

"Session" type (Page 8260)

"Nonce" type

Description

The `Nonce` type defines attributes of a nonce that are required to log in to a GraphQL client via SWAC login.

Attributes:

Name	Data type	Description
`value`	`String`	The nonce string
`validFor`	`Int`	Time span in seconds until the nonce instance expires

See also

"nonce" query (Page 8253)

"loginSWAC" mutation (Page 8251)

"Quality" type

Description

An instance of type `Quality` represents the quality of a tag value or alarm value (`value` attribute).

Attributes:

Name	Data type	Description
`quality`	`MainQuality`	The main QualityCode, as defined in enumeration `MainQuality`
`subStatus`	`QualitySubStatus`	The reason for the main QualityCode, as defined in enumeration `QualitySubStatus`
`limit`	`QualityLimit`	Information on whether or how the QualityCode is related to defined limit values, as defined in enumeration `QualityLimit`
`extendedSubStatus`	`QualityExtendedSubStatus`	More detailed information on `subStatus`, as defined in enumeration `QualityExtendedSubStatus`
`sourceQuality`	`Boolean`	The source that set `value` also set quality.
`sourceTime`	`Boolean`	The source that set `value` also set a time stamp.
`timeCorrected`	`Boolean`	The time stamp set by the source has been corrected.

"QualityInput" type

Description

The `QualityInput` type describes the attributes that are passed when `writeTags` is called in the input parameter `quality`.

Name	Data type	Description
`quality`	`MainQuality`	Mandatory specification The main QualityCode, as defined in enumeration `MainQuality`
`subStatus`	`QualitySubStatus`	The reason for the main QualityCode, as defined in enumeration `QualitySubStatus`

See also

"writeTags" mutation (Page 8239)

"Session" type

Description

The `Session` type defines attributes of a session.

Attributes:

Name	Data type	Description
`token`	`String`	ID of the authorization token for this session In subsequent server requests, pass the ID of the authorization token in the HTTP header `Authorization`, preceded by the `Bearer` prefix. When operations are called that require a user to be logged on to the server, this ID must be passed in the HTTP header `Authorization`, preceded by a `Bearer` prefix.
`expires`	`Timestamp`	Time at which the session expires, as `Timestamp` instance
`error`	`Error`	`Error` instance of possible item-level errors

See also

"session" query (Page 8253)

"UserGroup" type (Page 8262)

"User" type (Page 8262)

"login" mutation (Page 8250)

"extendSession" mutation (Page 8252)

"Error" type (Page 8258)

"TagValueNotification" type

Description

The `TagValueNotification` type defines which attributes the notifications for subscribed tags can contain.

Attributes:

Name	Data type	Description
`name`	`String`	Name of the subscribed tag
`value`	`Value`	`Value` instance of the tag

Name	Data type	Description
error	Error	Error instance of possible item-level errors
notificationReason	String	Possible values: • "Added" The subscription of the tag was started. The property values of the tag are sent at the start time of the subscription. • "Modified" The tag was modified. Your current property values are sent. • "Removed" The subscription of the tag was closed.

See also

"Error" type (Page 8258)

"tagValues" subscription (Page 8242)

"TagValueResult" type

Description

The TagValueResult type defines which attributes the server can supply in its response after the tagValues query is called.

Attributes:

Name	Data type	Description
name	String	Tag name
value	Value	Value instance of the tag
error	Error	Error instance of possible item-level errors

See also

"tagValues" query (Page 8238)

"Error" type (Page 8258)

"Value" type (Page 8263)

"Time span" type

Description

Type used to define a time span.

Data type of time span: RAW (integer in 100 ns)

See also

"ActiveAlarm" and "ActiveAlarmNotification" types (Page 8254)

"Time stamp" type

Description

Type for the definition of a time stamp according to ISO 8601 (https://en.wikipedia.org/wiki/ISO_8601).

See also

"ActiveAlarm" and "ActiveAlarmNotification" types (Page 8254)

"User" type

Description

The `User` type defines attributes of the user logged in to GraphQL.

Attributes:

Name	Data type	Description
`id`	`String`	User ID
`name`	`String`	User name
`groups`	`[UserGroup]`	The user group to which the users belong, as `UserGroup` instance
`fullName`	`String`	The full user name, such as first name and last name
`language`	`String`	The language set for the user in UMC Can be empty.
`autoLoggOffSec`	`Int`	Time period in seconds for which the user can be inactive before their authorization token expires

See also

"Session" type (Page 8260)

"UserGroup" type (Page 8262)

"UserGroup" type

Description

The `UserGroup` type defines attributes of a user group.

Attributes:

Name	Data type	Description
`id`	`String`	ID of the user group
name	`String`	Name of the user group

See also

"User" type (Page 8262)

"Value" type

Description

An instance of type `Value` represents a tag value.

Attributes:

Name	Data type	Description
`value`	`Variant`	The current process value
`timestamp`	`Timestamp`	Timestamp of the last change of `value`
`quality`	`Quality`	Quality of `value`

See also

"TagValueResult" type (Page 8261)

"Quality" type (Page 8259)

"TagValueNotification" type (Page 8260)

"WriteTagValueResult" type

Description

An instance of type `WriteTagValueResult` represents a feedback for the write access to a tag.

Attributes:

Name	Data type	Description
`name`	`String`	Tag name
`error`	`Error`	Error instance of possible item-level errors

See also

"writeTags" mutation (Page 8239)

"Error" type (Page 8258)

20.4.6 Code examples

Numerous code examples in multiple programming languages are included in the scope of delivery of WinCC Unified GraphQL.

Overview

Programming language	Covered topics
Python	Login Querying and changing data Subscribing to data
HTML and Javascript	Subscribing to data and displaying in Google diagrams
C#	Purely WebSocket-based subscription without GraphQL library
SWAC	Login with a SWAC-based login method

Installation

The GraphQL examples are an integral component of the Openness SDK and available on the WinCC Unified installation medium.

You can find information on installing the SDK in the "Installation SDK" user help.

20.4.7 Recommended procedures

20.4.7.1 Performance optimization

The performance capability of a GraphQL client depends on how the GraphQL API is being used.

Below are tips on how you can optimize the performance of your GraphQL application.

Limiting the selection

In its response to the client, the GraphQL server transmits the fields in the selection set that were specified by the client for the operation request. In most cases, fields that were not requested are not processed by the server.

Improve the performance of your client by using selection sets that are precisely tailored to your requirements.

Example

- `activeAlarms` query with extensive selection set:
```
query {activeAlarms(languages: ["en-US", "de-DE"]filterLanguage:
"en-US") {name instanceID alarmGroupID raiseTime
acknowledgmentTime clearTime resetTime modificationTime state
textColor backColor flashing alarmClassName alarmClassSymbol
alarmClassID stateMachine priority alarmParameterValues languages
alarmType eventText infoText alarmText1 alarmText2 alarmText3
alarmText4 alarmText5 alarmText6 alarmText7 alarmText8 alarmText9
stateText origin area changeReason connection valueLimit
sourceType suppressionState hostName userName value valueQuality
{ quality subStatus } quality { quality subStatus } invalidFlags
{ invalidAlarmParameter invalidConfiguration invalidEventText
invalidTimestamp } deadBand producer duration sourceID
systemSeverity loopInAlarm loopInAlarmParameterValues tag
userResponse } }
```
- `activeAlarms` query with limited selection set:
```
query { activeAlarms( languages: ["en-US", "de-DE"]
filterLanguage: "en-US" ) { name instanceID eventText } }
```

Bulk operations

Method calls of a web client have a larger overhead than method calls of locally connected DLLs or RPCs (Remote Procedure Calls) because a connection between the client and server has to be established in the background. This also applies to GraphQL.

Reduce this overhead by calling a method once and passing a list of objects as input parameter instead of individually calling the method for each object. The GraphQL server executes the operation for all objects from the list and supplies the result in a response.

Example

Objective	Read out the timestamp of multiple tags
Query	`query{ tagValues(names: ["Tag_1"],["Tag_2"],["Tag_3"]) {value {value timestamp} error { description }}`
Response	`{"data": {"tagValues": [{"value": {"value": 75, "timestamp": "2022-07-20T07:50:46.476" }, "error": {"description": "Succeeded" }}, {"value": {"value": false, "timestamp": "1970-01-01T00:00:00.000Z" }, "error": {"description": "Succeeded" }},{{"value": "value": false, "timestamp": "1970-01-01T00:00:00.000Z" }, "error": {"description": "Succeeded" }}]}}`

Tip for working efficiently

Change the same tag in the same mutation request multiple times.

Example: A GraphQL client is to document the values of a tag for audit purposes. The client subscribes to the tag and caches the reported value changes (value and timestamp). At regular intervals, the client executes a mutation to which it passes the cached values with their associated timestamps.

Using efficient client libraries

Libraries for GraphQL clients hide the details on HTTP and WebSockets from the developers. They convert the responses of the server into objects that correspond to the programming language, check whether the client code violates the schema, and more. This simplifies programming of a GraphQL client but slows down its execution.

How useful and performant a library is depends on which functions the library takes on, how well it is programmed and the programming language used.

Test a variety of libraries in advance before deciding which library is best suited to your needs.

Using a custom client

If performance is the most important factor, you can use the GraphQL API directly with an HTTP and/or WebSocket library instead of a client library.

Queries and mutations are HTTP POST messages in which the operation is sent in the POST body and the authorization in the HTTP header.

Subscriptions are WebSocket connections. Their input parameters are transferred as WebSocket messages.

You can examine the details of the messages, e.g. with the Google Chrome developer tools, while operations are executed in Apollo Studio.

20.4.7.2 Disconnection by server

Overview

Normally, the client closes the connection to the GraphQL server by requesting the `logout` mutation. In rare cases, the server closes the connection, e.g. when it is stopped.

When the server closes the connection, the GraphQL client library receives a notification regarding this. The client must reestablish the connection. If the server is still running, the client must execute the subscription again.

Handling of subscriptions after connection reestablishment

If the server is still running, the client can execute the subscription again.

If the server has been stopped, the client must cyclically query the server until it is available again, e.g. by executing the subscription operation until it is successful.

Examples

- Folder "Support\Openness\GraphQL\Examples\PythonClient" on the WinCC Unified installation medium contains the following code example: "gql_subscription.py"
  In the example, the iterator is closed and a specific exception is thrown.
- The following Python code snippet shows how the client closes the subscription and how it is notified when the server closes the subscription:

```
try:

  # Using `async with` on the client will start a connection on the transport
  # and provide a `session` variable to execute queries on this connection
  async with Client(
      transport=transport,
      fetch_schema_from_transport=True,
  ) as session:
      async for result in session.subscribe(subscription):
          print(result)

          counter += 1
          # this is just a dummy condition for exiting the loop and therefore closing the subscription
          # a real life condition would be e.g., checking a bool set from outside, when the user
          # clicks an "x" button to close the subscription window
          if counter == 10:
            print ("Closing connection from client side")
            break

except ConnectionClosed:
  print ("Connection closed by the server")
```

20.4.8 Troubleshooting

20.4.8.1 Top-level and item-level errors

Error groups

The following error groups exist in GraphQL:

- Top-level errors
  The entire method request has failed. Only the error message is supplied, and no result data.
- Item-level errors
  The method was able to be requested, but parts of the method call were not successful. Result data is supplied. The parts of the method request that were not successful contain an error code other than "0" in the `error` attribute and an error description other than "Succeeded".

Note

Error attributes specified in the selection set

In order for the server response to contain error information about item-level errors, you must request the desired error attributes when calling the operation with the selection set.

It is recommended that the `code` or `description` attribute, or both, be requested.

Example for a top-level error

If the requested language is invalid, this results in the following error message:

```
{
  "errors": [
  {
      "message": "At least one of the requested languages is
invalid.",
      "locations": [
        {
          "line": 2,
          "column": 3
        }],
      "path": ["activeAlarms"],
      "extensions":
      {
        "code": "INTERNAL_SERVER_ERROR"
      }
  }],
  "data":
  {
    "activeAlarms": null
  }
}
```

Attributes:

- `message`: Easy-to-understand error description
- `locations` and `path` The part of the query that contains errors
- `code`: A general or specific error code
  `INTERNAL_SERVER_ERROR` is the default error code if no specific error code exists.
- (when development mode is enabled) `stackTrace`: For further error diagnostics

Example for an item-level error

A writeTagValues call is to write values to two tags. The write operation was able to be successfully performed for tag "TrainingString1" but not for tag "Intern_Int_2". The result data for "Intern_Int_2" contains the error code and an error description. The reason for the error is that the passed data type (String) could not be converted to the expected data type (DTInt):

```
{
  "data": {
    "writeTagValues": [
      {
        "name": "TrainingString1",
        "error":
        {
          "code": "0",
          "description": "Succeeded"
        }
      },
      {
         "name": "Intern_Int_2",
         "error":
         {
           "code": "201",
           "description": "Can't convert provided value to data type
'DTInt': 'failing string value'"
         }
       }]
  }
}
```

20.4.8.2 GraphQL server doesn't start

Problem	GraphQL server doesn't start
Identify the cause	1. In the installation folder of WinCC Unified, double-click the "RTILtraceViewer.exe" file under "WinCCUnified\bin". The "TraceViewer" application is started. 2. Browse the traces for the trace entry documenting the failed start of the GraphQL server.
Examples of possible causes	• The port configured for the GraphQL server is being used by another application. • A configured plug-in could not be loaded.

Port occupied

If the port needed for the GraphQL server is being used by another application, the GraphQL server cannot start.

Resulting trace entry:

- Severity "Fatal"
- Message: "Port 4000 already in use. Exiting..."

Remedy: Select a different port for the other application.
